Re: North Dakota State Implementation Plan Revision for Regional Haze

Dear Administrator Regan:

The State of North Dakota is hereby submitting an update to North Dakota's State Implementation Plan (SIP) which addresses the requirements for Regional Haze under Section 308 of 40 Code of Federal Regulations (CFR) Part 51, Requirements for Preparation, Adoption, and Submittal of Implementation Plans, Subpart P – Protection of Visibility. This SIP package was prepared for the second round of the Region Haze Regulation by the North Dakota Department of Environmental Quality, Division of Air Quality.

As outlined in the SIP package, North Dakota has made significant progress toward the 2064 visibility end goals resulting from the implementation of the first round of the Regional Haze requirements. A significant portion of the progress is attributed to North Dakota's electrical generating utilities reducing emissions of sulfur dioxide by approximately 102,000 tons (down 72%) and nitrogen oxides by approximately 41,600 tons (down 55%) from 2002 to current representative rates.

As required, a periodic progress report is also included with this SIP package. North Dakota has determined that the Regional Haze SIP revision achieves the goals for visibility improvement and includes enforceable emission reductions. The information included with this SIP package provides the support for this declaration.

With this submission, I am requesting the United States Environmental Protection Agency's approval of this SIP package.

If you have any questions regarding this submittal, please contact James Semerad, Air Quality Division Director for the North Dakota Department of Environmental Quality, at 701-328-5179 or jsemerad@nd.gov.

With Gratitude,

A handwritten signature in blue ink, reading "Doug Burgum". The signature is fluid and cursive, with a long horizontal stroke at the end.

Re: North Dakota State Implementation Plan Withdrawal Regarding Regional Haze

Dear Administrator Regan:

The State of North Dakota is hereby withdrawing the State Implementation Plan (SIP) Supplement No. 2 for Coal Creek Station which the state submitted to the Environmental Protection Agency on January 2, 2013.

Concurrent with this withdrawal, the State of North Dakota has submitted a revised nitrogen oxides Best Available Retrofit Technology (BART) determination for Coal Creek Station within the North Dakota State Implementation Plan Revision for Regional Haze. The North Dakota State Implementation Plan Revision for Regional Haze was prepared for the second round of the Regional Haze Regulations. Appendix F of the North Dakota State Implementation Plan Revision for Regional Haze contains the revised nitrogen oxides BART for Coal Creek Station and associated proposed permit to construct.

If you have any questions regarding this action, please contact James Semerad, Air Quality Division Director for the North Dakota Department of Environmental Quality, at 701-328-5179 or jsemerad@nd.gov.

With Gratitude,

A handwritten signature in blue ink, reading "Doug Burgum".

Executive Summary

The federal Regional Haze Rule (RHR) requires North Dakota to address regional haze in each mandatory Class I Federal area (CIA) located within North Dakota and in each mandatory CIA located outside North Dakota, which may be affected by emissions from within North Dakota. Under the RHR, North Dakota is required to submit a State Implementation Plan (SIP) addressing the specific elements required by the RHR. This document includes the State of North Dakota's SIP submittal to the U.S. Environmental Protection Agency (EPA) Region 8 to meet the requirements of RHR Section 308 (40 CFR Part 51, Subpart P, Section 51.308). This submittal is a revision to the regional haze SIP that North Dakota submitted for the first round of the RHR. Adoption of the North Dakota SIP revision for regional haze amends the Implementation Plan for the Control of Air Pollution for the State of North Dakota.

The RHR requires North Dakota to demonstrate the progress made to date and determine any additional progress needed to achieve the visibility improvement goals established for this planning period. North Dakota is required to set reasonable progress goals which 1) must provide for an improvement in visibility for the most impaired days over the period of the implementation plan and 2) ensure no degradation in visibility for the clearest days over the same period. This SIP revision analyzes the current rate of progress needed to attain natural visibility in CIAs by the year 2064 and examines the need to implement additional emission reduction measures on any sources which are reasonably anticipated to contribute to visibility impairment. For all such sources, potential additional emission reductions are determined through identification of available and technically feasible control measures. These available and technically feasible controls are further examined in consideration of the four statutory factors. The four factors are: 1) cost of compliance, 2) time necessary for compliance, 3) energy and non-air quality environmental impacts, and 4) remaining useful life.

North Dakota reviewed all sources of significance in the state and chose ten existing sources to analyze for additional potential emission reduction measures as part of North Dakota's development of its four-factor analysis. Each source was required to submit a report North Dakota detailing the additional emissions reduction measures that are available and technically feasible for implementation, in consideration of the four factors. These measures were reviewed by North Dakota and used by North Dakota to determine what is necessary to demonstrate reasonable progress in consideration of the four statutory factors. North Dakota chose these sources based on recent representative emissions of nitrogen oxides (NO_x) plus sulfur dioxide (SO₂) and proximity to CIAs, known as a Q/d screening analysis. Projected future emissions were also considered when evaluating North Dakota impacts to in- and out- of state CIAs. Of the ten facilities selected, six are coal fired electrical generating utilities (EGUs) and four are non-EGUs.

During the first round of RHR, three of the six coal fired EGU facilities were subject to the RHR's Best Available Retrofit Technology (BART) requirements. The three remaining coal fired EGUs were not subject to BART requirements, but were required by North Dakota to undertake projects necessary for reasonable progress. The BART and reasonable progress requirements significantly reduced NO_x and SO₂ emissions from North Dakota sources. The total reductions from North Dakota EGUs were approximately 102,000 tons of SO₂ (down 72%) and 41,600 tons of NO_x (down 55%) from 2002 to current representative emission levels.

Of the three non-BART EGU sources, one retired in early 2022 (Heskett Station) and the other two are projected to remain online and continue to operate consistently with recent operations (Antelope Valley Station and Coyote Station). For these two sources, additional controls were selected for evaluation using model simulations to project the impact additional controls on these sources would have on visibility in North Dakota CIAs. The controls selected for review were determined in consideration of the four factors, the source's existing level of control, recent NO_x and SO₂ emission rates, and costs of controls as compared to round 1 costs incurred by similar sources (adjusted to 2018 dollars). In short, the four factor controls selected for modeling evaluation on these two sources would reduce the NO_x and SO₂ performance rates to levels more consistent with the North Dakota BART EGU sources.

The Department used modeling to project the 2028 visibility conditions at the CIAs located within and around North Dakota. The 2017 revisions to the RHR added a provision that allows states to propose an adjustment to the uniform rate of progress¹ (glidepath) to account for impacts from anthropogenic sources outside the United States. In evaluating the causes and contributions of visibility impairment in North Dakota CIAs, North Dakota determined that anthropogenic sources outside the United States contribute a minimum of 40% of the total (non-Rayleigh²) projected 2028 light extinction at North Dakota CIAs, meaning this adjustment is significant to North Dakota. As such, North Dakota exercised its authority to adjust its glidepaths pursuant to 40 CFR §51.308(f)(1)(vi)(B). With the glidepath adjustment, the baseline 2028 visibility condition projections³ for CIAs in and around North Dakota indicates that all areas are expected to meet the 2028 planning goals.

Modeling the projected 2028 visibility conditions with additional emissions reduction measures selected from the four-factor analysis sources (Antelope Valley Station and Coyote Station) did not show a reduction in anthropogenic visibility impairment⁴ from the projected baseline 2028 visibility conditions for the most impaired days⁵. The additional emissions reduction measures modeling was conducted using two scenarios determined from the four-factor analyses. The first scenario included over 22,000 tons of combined NO_x and SO₂ reductions at a capital cost of approximately \$150 million and an annualized cost of approximately \$30 million. The first scenario resulted in a projected improvement to baseline 2028 visibility of 0.1 deciview⁶ at Lostwood Wilderness Area and 0.08 deciviews at Theodore Roosevelt National Park. The second scenario included over 7,000 tons of combined NO_x and SO₂ reductions at a capital cost of approximately \$0.5 million and an annualized cost of approximately \$2 million. The second scenario resulted in a projected improvement to baseline 2028 visibility of 0.04 deciview at Lostwood Wilderness

¹ Uniform rate of progress is the linear improvement in visibility from the baseline visibility conditions to natural visibility conditions for the most impaired days.

² Rayleigh refers to the light scattering of the natural gases in the atmosphere.

³ Baseline 2028 visibility conditions are projected using expected 2028 emissions projections without additional emissions reduction measures selected from the four factors.

⁴ Anthropogenic visibility impairment means any humanly perceptible difference due to air pollution from anthropogenic sources between actual visibility and natural visibility on one or more days. Because natural visibility can only be estimated or inferred, visibility impairment also is estimated or inferred rather than directly measured.

⁵ Most impaired days means the twenty percent of monitored days in a calendar year with the highest amounts of anthropogenic visibility impairment.

⁶ A deciview is the unit of measurement on the deciview index scale for quantifying in a standard manner human perceptions of visibility.

Area and 0.03 deciviews at Theodore Roosevelt National Park. Neither additional emissions reduction measures scenario indicated the North Dakota CIAs would experience a reduction in anthropogenic visibility impairment from the installation of these potential control measures. The modeling analysis also indicated there will be no degradation during the clearest days⁷ projection of the baseline 2028 visibility conditions.

North Dakota is currently projected to meet its 2028 visibility goals and is projected to remain on track to meet the 2064 visibility goals (below the adjusted glidepath). Continuing to remain below an adjusted glidepath and showing improvement on the most impaired days for each planning period will accomplish the 2064 end goals. North Dakota has determined that the additional emissions reduction measures selected upon four-factor consideration will not provide for a reduction in anthropogenic visibility impairment on the most impaired days visibility projections for 2028. Therefore, the Department determined that it is not reasonable to require these additional control measures during this planning period. Accordingly, the 2028 reasonable progress goals for the most impaired days in the North Dakota CIAs are established at 15.8 deciviews for Lostwood Wilderness Area and 13.6 deciviews for each unit of Theodore Roosevelt National Park. The Department will continue to monitor North Dakota's CIA visibility progression and provide an update in its 2025 progress report.

This proposed SIP revision meets the statutory requirements of 40 CFR Part 51, Subpart P, Section 51.308. This proposed SIP revision describes and documents rules, regulations, and additional measures that are included in the long-term strategy. The information contained in this SIP revision supports North Dakota's determination that the additional emission reduction measures selected for review in consideration of the four factors are not reasonable for implementation during this planning period (second round of the RHR).

The RHR also requires each State to consult with other states and Federal Land Managers (FLM) as part of the regional haze SIP development process. States are required to share information with other states that have CIAs that are reasonably anticipated to be impacted by emissions from North Dakota. States are also required to evaluate (though not necessarily implement) control measures requested by other states and document actions taken to resolve disagreements. In addition to these requirements, North Dakota chose to consult with Tribal partner stakeholders in and near North Dakota. Doing so allowed North Dakota sufficient time to meaningfully engage and gather input from our Tribal partners. State and sector category source apportionment modeling indicated that neighboring state CIAs are not significantly impacted by emissions from North Dakota. Additionally, the modeling indicated that neighboring state sources were not significantly impacting visibility in North Dakota CIAs. Documentation is included in Section 3 and Appendix C. North Dakota requested feedback from the states of Minnesota, Montana, and South Dakota on these determinations in June 2021. North Dakota has not received responses from neighboring states regarding this determination. North Dakota also held consultation webinars in late 2020 with National Park Service and the US Forest Service to share preliminary modeling results, the method for selecting sources for additional emissions reduction measures review in consideration of the

⁷ Clearest days means the twenty percent of monitored days in a calendar year with the lowest values of the deciview index.

four factors, the sources selected, and North Dakota current strategy based on the information available. Documentation is included in Appendix E.

North Dakota held an early engagement consultation period for the FLMs, and other stakeholders listed above, from September 20, 2021, through November 19, 2021. In addition to the early consultation, a video conference meeting was held on November 10, 2021. The objective of the meeting was to discuss the proposed SIP revision. Attendees included the NDDEQ, National Park Service, U.S. Forest Service, and EPA region 8. This engagement provided the stakeholders with a formal opportunity to review and comment on North Dakota's proposed SIP revision. Comments were received from the National Parks Service and the U.S. Forest Service in November 2021 and are included in Appendix D.2. A response to the FLM comments is included in Appendix D.2.c. Additional text explaining the North Dakota's SIP development process has been included in Section 2.1 to address FLM feedback.

Comments were received from EPA Region 8 on January 13, 2022, and on June 1, 2022, and are included in Appendix D.4. and Appendix D.6, respectively. All comments received are included in Appendix D.6 (including EPA comments). A response to comments document has been included in Appendix D.5.

Air Quality in North Dakota

The federal Clean Air Act (CAA) establishes “a comprehensive national program that makes the States and the Federal government partners in the struggle against air pollution”.⁸ The CAA also recognizes that “air pollution prevention (that is, the reduction or elimination, through any measures, of the amount of pollutants produced or created at the source) and air pollution control at its source is the primary responsibility of States and local governments.”⁹ In North Dakota, the North Dakota Department of Environmental Quality (NDDEQ) is the agency that designs and implements State and Federal air quality programs.¹⁰ North Dakota has successfully designed, implemented, and enforced air quality programs which has resulted in North Dakota being one of four States that comply with all National Ambient Air Quality Standards (NAAQS).¹¹ NAAQS are determined using scientific studies for the purpose of protecting human health and the environment. NDDEQ develops an annual ambient monitoring network plan and data summary report containing the detailed information on North Dakota’s ambient air quality monitoring.¹²

For the CAA’s Visibility Protection Program in Sections §§169, 169A, and 169B, North Dakota relies on the Interagency Monitoring of Protected Visual Environments (IMPROVE) network to monitor and determine the visibility conditions in Theodore Roosevelt National Park (TRNP) and Lostwood National Wildlife Refuge Wilderness Area (LWA). North Dakota will continue to rely on the IMPROVE network for its monitoring strategy for the RHR. In addition to the IMPROVE data covered in Sections 3.2, 3.3, 5.1, and Appendix C, North Dakota is supplementing this with data from North Dakota’s ambient air quality monitors that operate at TRNP (North Unit “NU” and South Unit “SU”), LWA, Bismarck and Fargo (North Dakota’s two largest cities). Bismarck and Fargo are being presented for comparison of the population centers to the CIAs with respect to the NAAQS. The supplemental data includes the monitoring of Nitrogen Dioxide (NO₂), SO₂, particulate matter with diameters that are generally less than 2.5 micrometers. (PM_{2.5}), and Ozone, which are the species of interest for regional haze planning in North Dakota.

This information is being provided to demonstrate North Dakota is well in compliance with all NAAQS standards, to show air quality trends since the early 2000’s, and as additional support of North Dakota’s stance in this SIP revision. North Dakota takes pride in maintaining high quality air and being in attainment/unclassifiable with all NAAQS standards. The NAAQS data is presented in Figure 1 through Figure 7 as follows:

- NO₂
 - Primary 1-hour. 98th percentile of 1-hour daily maximum concentrations, averaged over 3-years. Standard of 100 parts per billion (ppb).
 - Primary and Secondary 1-year. Annual mean concentration. Standard of 53 ppb.

- SO₂
 - Primary 1-hour. 99th percentile of 1-hour daily maximum concentrations, averaged over 3-years. Standard of 75 ppb.
 - Primary 1-year. Annual mean concentration. Standard of 30 ppb.¹³
- PM_{2.5}
 - Primary 1-year. Annual mean averaged over 3-years. Standard of 12 micrograms per meter cubed (µg/m³).
 - Primary and Secondary 24-hour. 98th percentile of 24-hour average, averaged over 3-years. Standard of 35 µg/m³.
- Ozone
 - Primary and Secondary 8-hour. Annual 4th highest daily maximum 8-hour concentration averaged over 3-years. Standard of 70 ppb.

Figure 1: NO₂ Annual Average Ambient Concentrations

¹³ Shown for informational purposes. Standard was revoked with 77 FR 35520. Available at: <https://www.govinfo.gov/content/pkg/FR-2010-06-22/pdf/2010-13947.pdf> (Last visited June 22, 2021).

Figure 2: NO₂ 98th Percentile of Daily Maximum 1-hour Concentration

Figure 3: SO₂ Annual Average Ambient Concentrations

Figure 4: SO₂ 99th Percentile of Daily Maximum 1-hour Concentration

Figure 5: PM_{2.5} Annual Average Ambient Concentration

Figure 6: PM_{2.5} 98th Percentile of Average 24-hour Concentration

Figure 7: Ozone 4th High of 8-hour Concentration

As illustrated in Figure 1 through Figure 7 for the ambient monitors located at TRNP (North and South Units), LWA, Bismarck and Fargo, North Dakota is meeting all NO₂, SO₂, PM_{2.5}, and Ozone NAAQS standards.

The NO₂ data shown in Figure 1 and Figure 2 demonstrates North Dakota is well in compliance with the NO₂ NAAQS. For the years of 2002–2020:

- Figure 1, LWA and TRNP-NU have each averaged an annual NO₂ concentration of under 2ppb, significantly below the 53ppb standard.
- Figure 2, LWA and TRNP-NU have an average 98th percentile of daily maximum 1-hour concentrations of 14ppb and 9ppb, respectively, significantly below the 100ppb standard.
- For both the annual and the 98th percentile standards, NO₂ concentrations have remained very stable since 2002.

The SO₂ data shown in Figure 3 and Figure 4 demonstrates North Dakota is well in compliance with the SO₂ NAAQS. For the years of 2002–2020:

- Figure 3, LWA, TRNP-NU, and TRNP-SU have each averaged an annual SO₂ concentration of 1ppb or lower, significantly below the revoked 30ppb standard.
- Figure 4, LWA, TRNP-NU, and TRNP-SU have an averaged 99th percentile of daily maximum 1-hour concentrations of 33ppb, 12ppb, and 6ppb, respectively, significantly below the 75ppb standard. These averages are even smaller for the years of 2014–2020.
- For the 99th percentile standards, SO₂ concentrations have been on a downward trend since 2010. A pronounced decline is seen from 2010–2014, with less of a decline from 2014–2020. SO₂ annual ambient concentrations have remained very stable since 2002.

The PM_{2.5} data shown in Figure 5 and Figure 6 demonstrates North Dakota is well in compliance with the PM_{2.5} NAAQS. For the years of 2002–2020:

- Figure 5, LWA, TRNP-NU, and TRNP-SU have each averaged an annual PM_{2.5} concentration of 5 µg/m³ or lower, significantly below the 12 µg/m³ standard.
- Figure 6, LWA, TRNP-NU, and TRNP-SU have an averaged 98th percentile of daily maximum concentrations of 18 µg/m³, 16 µg/m³, and 14 µg/m³, respectively, significantly below the 35 µg/m³ standard.

The ozone data shown in Figure 7 demonstrates North Dakota is well in compliance with the ozone NAAQS. For the years of 2002–2020:

- Figure 7, LWA, TRNP-NU, and TRNP-SU have an averaged 4th highest daily maximum 8-hour concentration of 58ppb, 60ppb, and 58ppb, respectively, significantly below the 70ppb standard.
- The 4th highest daily maximum 8-hour ozone concentration has remained very stable since 2002.

North Dakota continues to achieve excellent levels of air quality for NO₂, SO₂, PM_{2.5}, and ozone. Trends show ambient monitor concentrations have remained stable or declined since the early 2000's, indicating

recent developmental activity in North Dakota has not adversely affected the air quality in TRNP, LWA, or at any other state approved ambient monitoring locations. North Dakota anticipates these monitoring trends will continue. North Dakota will continue to monitor the ambient air and utilize the IMPROVE network data to track the air quality conditions in North Dakota and, if necessary, take further action in the 2025 progress report.

1 Background and Overview of The Federal Regional Haze Rule

Section 169(A) of the Clean Air Act (CAA) establishes the national visibility goal of “the prevention of any future, and the remedying of any existing, impairment of visibility in mandatory CIAs which impairment results from manmade air pollution.” Based on the requirements of Section 169(A), the North Dakota Department of Environmental Quality (Department)¹⁴ developed a State Implementation Plan (SIP) to address the national visibility goal. The first round Regional Haze SIP was submitted to the EPA in March 2010. The first periodic progress update was submitted in January 2015. The second round RH SIP with an updated progress report is included with this SIP revision.

The RHR was promulgated by EPA in July 1999. The RHR has subsequently been amended, with the most recent amendment in January 2017. The RHR requires that States adopt State Implementation Plans (SIPs) to address visibility impairment in each of the 156 Mandatory CIAs across the nation, Figure 8.

The RHR’s two key requirements are to improve visibility in CIAs for the days that have the most impaired visibility and to ensure that there is no degradation in visibility for the clearest days. The end goal of the RHR is to attain natural visibility conditions in all CIAs by 2064.

Figure 8: Class I areas in the United States¹⁵

¹⁴ On April 29, 2019, the Department of Environmental Quality went into effect and assumed authority for the environmental protection programs that had previously been under the former Department of Health Environmental Health Section’s authority. See 2017 N.D. Sess. Laws ch. 199, §1. The air pollution control statutes have moved from N.D.C.C. ch. 23-25 to 23.1-06, and the rules have moved from N.D. Admin. Code art. 33-15 to 33.1-15.

¹⁵ Available at: <https://www.epa.gov/visibility/regional-haze-program> (Last visited February 23, 2021)

North Dakota's RH SIP for the first planning implementation period was submitted to EPA on March 3, 2010. The EPA determined the SIP submittal was complete on April 13, 2010. Supplement No. 1 to the SIP was submitted to EPA on July 27, 2010 and Amendment No. 1 was submitted on July 28, 2010. On September 21, 2011, the EPA proposed a partial approval and partial disapproval of the SIP. At the same time, EPA proposed a Federal Implementation Plan (FIP). On April 6, 2012, EPA finalized its approval of various portions of the SIP and a FIP for those items not considered approvable.¹⁶ The FIP established NO_x limits for Coal Creek Station different than those the Department had proposed. However, the Coal Creek best available retrofit technology (BART) FIP was vacated by the Eighth Circuit Court of Appeals.¹⁷ On April 26, 2018 EPA proposed to approve North Dakota's BART determination for Coal Creek.¹⁸ EPA did not take final action on the proposed approval. North Dakota, EPA, and Coal Creek were working to address this until Great River Energy announced the retirement of Coal Creek Station. On June 30, 2021 Great River Energy announced it had an agreement with Rainbow Energy Center, LLC (REC) to purchase Coal Creek. As a result, the Department has determined the appropriate course of action is to move forward with proposing a NO_x BART for Coal Creek Station. This proposed action is included with this SIP revision. Section 8 provides the supplemental information regarding the Department's proposed NO_x BART for Coal Creek Station. Also included with this SIP revision is a proposed permit to construct which includes the enforceable conditions needed to satisfy the BART requirements.

The RH SIP for the first planning implementation period identified both current visibility impairment and natural conditions for the 20% haziest days (now the most impaired days) and the 20% best days (also known as the clearest days or least impaired days). Based on these results, the amount of visibility improvement that is required to achieve the national visibility goal and the uniform rate of progress were calculated (Section 3).

Pursuant to 40 CFR §51.308(f), each periodic comprehensive revised SIP is intended to meet the requirements of the EPA's RHR that were adopted to comply with CAA Section 169A. As is required by 40 CFR §51.308, this SIP addresses:

- 40 CFR 51.308(a) What is the purpose of this section? This section establishes the requirements for RH SIP, these requirements are included throughout this RH SIP.
- 40 CFR 51.308(b) When are the first implementation plans due under the regional haze program? Completed for first round of regional haze, no action required under this RH SIP.
- 40 CFR 51.308(c) [Reserved], no action.
- 40 CFR 51.308(d) What are the core requirements for the implementation plan for regional haze?
 - 40 CFR 51.308(d)(1) Reasonable progress goals, Section 3.1 and Section 6.
 - 40 CFR 51.308(d)(2) Calculations of baseline and natural visibility conditions, Section 3.2.1 and 3.2.2.
 - 40 CFR 51.308(d)(3) Long-term strategy for regional haze, Section 5

 - 40 CFR 51.308(f)(5) “plan revision to serve as progress report”, Section 6.7
 - 40 CFR 51.308(f)(6) Monitoring strategy and other implementation plan requirements, Section 6.8.
- 40 CFR 51.308(g) Requirements for periodic reports describing progress towards the reasonable progress goals, Section 9.
- 40 CFR 51.308(h) Determination of the adequacy of existing implementation plan, Section 5.2, Section 5.3, and Section 6.1
- 40 CFR 51.308(i) What are the requirements for State and Federal Land Manager coordination?, Section 2.1.1.

1.1 Class I Areas (CIAs) in North Dakota

The CIAs in North Dakota are: the Theodore Roosevelt National Park (TRNP) which consists of three separate, distinct units and the Lostwood Wildlife Refuge Wilderness Area (LWA). Each of these CIAs are displayed in Figure 9.

Figure 9: Class I areas in North Dakota

1.1.1 Theodore Roosevelt National Park (TRNP)

TRNP is located within Billings and McKenzie Counties in North Dakota. The colorful badlands and Little Missouri River of western North Dakota provide the scenic backdrop to the park which memorializes the 26th president for his enduring contributions to the conservation of our nation's resources. The Park contains 70,447 acres divided among three separate, distinct units: South Unit, Elkhorn Ranch and North Unit. TRNP is managed by the National Park Service. TRNP is comprised of badlands, open prairie and hardwood draws that provide habitat for a wide variety of wildlife species including bison, prairie dogs, elk, deer, big horn sheep and many other wildlife species. The Little Missouri River passes through the three units of the park.

1.1.2 Lostwood National Wildlife Refuge Wilderness Area (LWA)

LWA is located in Burke County in the northwestern part of the State. Created by an act of Congress in 1975, LWA covers an area of 5,577 acres. LWA is managed by the U.S. Fish and Wildlife Service. LWA was designated in order to preserve a region well known for numerous lakes and mixed grass prairie and is home to one of the finest waterfowl breeding regions in North America.

1.2 Regional Haze Characteristics and Effects

1.2.1 Interagency Monitoring of Protected Visual Environments (IMPROVE) Program

The IMPROVE program¹⁹ was initiated in 1985. The IMPROVE program established baseline visibility conditions in all 156 CIAs at the time of the program's initiation. The IMPROVE program has since created a long-term monitoring program that tracks changes in visibility through time and works to determine the causal mechanisms for any visibility impairment in CIAs.

The IMPROVE program is operated and maintained through a formal cooperative relationship between the EPA, the National Park Service (NPS), the U.S. Fish and Wildlife Service (FWS), the Bureau of Land Management (BLM), National Oceanic and Atmospheric Administration (NOAA), and the U.S. Forest Service (USFS). Several additional organizations joined the effort in 1991 including the National Association of Clean Air Agencies, the Western States Air Resources Council (WESTAR), the Mid-Atlantic Regional Air Management Association (MARAMA), and the Northeast States for Coordinated Air Use Management (NESCAUM).

IMPROVE sites are located across the United States (Figure 10). Note the zoomed in view of the locations of the two IMPROVE sites in North Dakota shown in Figure 9. Each CIA in North Dakota has an IMPROVE site. North Dakota CIA IMPROVE sites were installed on December 15, 1999 at LWA and TRNP.

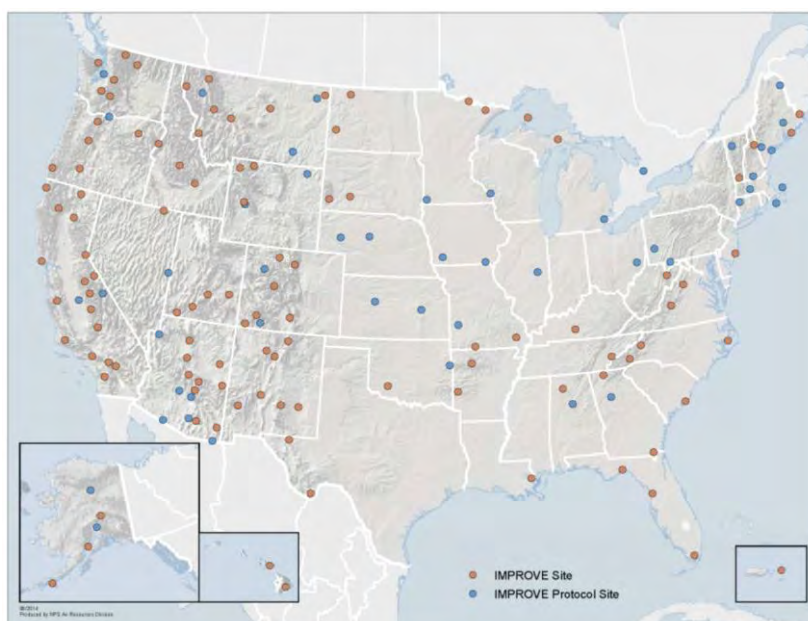

Figure 10: Locations of IMPROVE monitoring sites.²⁰

¹⁹ Available at: <http://vista.cira.colostate.edu/Improve/> (last visited July 6, 2021)

²⁰ Figure Available at: <http://vista.cira.colostate.edu/Improve/improve-program/>. Note that the map includes both “IMPROVE Sites” and “IMPROVE Protocol Sites”. The IMPROVE protocol sites are separately sponsored by state, regional, tribal, and national organizations. Both the IMPROVE sites and the IMPROVE protocol sites use identical samplers and analysis protocols by the same contractors, allowing all data to be treated equally.

The IMPROVE program has developed methods for estimating light extinction from speciated aerosol and relative humidity data. The three most common metrics used to describe visibility impairment are illustrated in Figure 11 and described below:

- Extinction (b_{ext}): Extinction is a measure of the fraction of light lost per unit length along a sight path due to scattering and absorption by gases and particles. Extinction is expressed in inverse Megameters (Mm^{-1}). Extinction is used to represent the contribution of each aerosol species to visibility impairment and can be practically thought of as the units of light lost over a distance of one million meters.
- Visual Range: Visual range is the greatest distance a large black object can be seen on the horizon. Visual range is expressed in kilometers (km) or miles (mi).
- Deciview (dv): Deciviews are the metric used for tracking regional haze in the RHR. The deciview index was designed to be linear with respect to human perception of visibility. A one deciview change is approximately equivalent to a 10% change in extinction in either direction. One deciview of change in visibility is generally considered to be the minimum change that the average person can detect with the naked eye.

Figure 11: Comparison of extinction (Mm^{-1}), deciview (dv), and visual range (km) ²¹

1.3 Regional Haze in North Dakota

Visibility in North Dakota's CIAs is impaired by both natural and manmade (anthropogenic) emission sources. Anthropogenic emissions sources include electric utility steam generating units (EGUs), area and point source oil and gas (O&G) operations, agricultural production and processing, on-road and non-road mobile sources, rail operations, prescribed burning, fugitive dust, and other minor sources. Naturally occurring emissions include U.S. and international wildfires, windblown dust, biogenic NO_x and volatile organic compounds (VOC), lightning NO_x , and other minor sources. The predominant emissions that may lead to visibility impairment are SO_2 , NO_x , particulate matter (PM_{10} and $\text{PM}_{2.5}$), VOCs, and ammonia (NH_3).

1.3.1 Anthropogenic Emissions Reductions from Round 1 of the RHR

During the first implementation period of the RHR, North Dakota accomplished significant reduction in anthropogenic emissions of PM, NO_x and SO_2 from coal fired EGUs. The applicable requirement, emissions limit, and date these controls were installed are included in Table 1.

²¹ Available at: http://vista.cira.colostate.edu/Improve/wp-content/uploads/2016/03/Intro_to_Visibility.pdf. (Last Visited May 18, 2021)

Table 1: BART and Reasonable Progress Success since Round 1 Implementation

Source	Unit	Pollutant	Applicable Requirement	BART/RP Limit ^A	Date Implemented (Month Year)
Antelope Valley	1	NO _x	RP (FIP)	0.17 lb/10 ⁶ Btu	May 2014

		NO _x	BART	0.15 lb/10 ⁶ Btu	Pending, proposed with this SIP Revision
		PM	BART	0.07 lb/10 ⁶ Btu	April 2017
R.M. Heskett ^D	2	SO ₂	RP	0.60 lb/10 ⁶ Btu	June 2016

^A Based on a 30-day rolling average unless otherwise noted.

^B As an alternative, the source may comply with a 95% reduction requirement.

^C As an alternative, M.R. Young 2 may comply with an alternative limit of 0.15 lb/10⁶ Btu and 90% reduction.

^D MDU is shutting down R.M. Heskett Units 1 and 2 in 2022.

The BART and reasonable progress requirements listed in Table 1 significantly reduced NO_x and SO₂. The total reductions from North Dakota EGUs were approximately 102,000 tons of SO₂ (down 72%) and 41,600 tons of NO_x (down 55%) from 2002 to current representative emissions²². These reductions are depicted in Figure 12 and listed in Table 2.

Figure 12: North Dakota Coal Fired EGU Emissions since from 2002-2019.

Table 2: North Dakota Coal Fired EGU Emissions and Reductions since 2002.

Facility	Unit	NO _x Emissions			SO ₂ Emissions		
		2002	RepBase	Reduction	2002	RepBase	Reduction

Total		76,127	33,373	56%	141,156	39,242	72%

²² Current representative emissions are detailed in Section 4.1.4.

1.3.2 Anthropogenically Most Impaired Days Conflict with Actual Visibility Impairment

The Department compiled the National Park Service's visitation statistics²³ at TRNP and compared the visitation to the EPA selected Most Impaired Days (MID)²⁴ and the average light extinction experienced at TRNP. When reviewing this data, it is apparent that focusing on the MID for TRNP will not meaningfully improve visibility or a visitor's experience in TRNP. Figure 13 displays the average monthly recreational visitors to TRNP from the years of 2014–2018 compared to the total number of MID and the average monthly light extinction.

As illustrated in Figure 13, TRNP receives 75% of the yearly visitation in the months of June, July, August, and September. During these same months there were a total of four MIDs identified, accounting for less than 4% of the total MIDs from 2014–2018. This indicates that during the highest levels of visitation, TRNP visibility is not being significantly impaired by anthropogenic emissions. This is supported when looking at the average light extinction over the same high visitation months versus the low visitation months. During high visitation months, TRNP experiences an average of 28 Mm^{-1} of light extinction versus 19 Mm^{-1} during low visitation months. The primary reason for the increased visibility impairment is from out of state wildfire activity. Further, the primary months which North Dakota has the highest number of MIDs (November–March) are months where the prevailing wind directions throughout much of North Dakota are from the West and Northwest. In other words, it is reasonable to assume the MIDs are attributable to international transport and not from North Dakota sources as many of the sources are downwind of the CIAs. The supporting wind rose data from North Dakota's ambient network can be found in NDDEQ's "Annual Reports & Monitoring Network Plans".²⁵

²³ Available at: <https://irma.nps.gov/STATS/SSRSReports/Park%20Specific%20Reports/Visitation%20by%20Month> (Last visited July 21, 2021)

²⁴ Most impaired days means the twenty percent of monitored days in a calendar year with the highest amounts of anthropogenic visibility impairment.

²⁵ Available at: <https://www.deq.nd.gov/AQ/monitoring/>. Under "Annual Reports & Monitoring Network Plans", select report year. See Appendix D, "Wind and Pollution Roses". (Last visited July 21, 2021)

Theodore Roosevelt National Park Visitation and Impairment 2014-2018

Figure 13: Monthly TRNP Visitation, Identified MIDs, and Average Light Extinction from 2014–2018.

1.4 General Planning Provisions

1.4.1 SIP Submission Dates

40 CFR §51.308(f) requires that States revise and submit their regional haze plan revisions to the EPA by July 31, 2021, July 31, 2028, and every 10 years thereafter. 40 CFR Section §51.308(g) requires that states submit a progress report five years after each SIP revision in order to evaluate progress toward the reasonable progress goals (RPG) for each applicable mandatory CIA. North Dakota's first progress report was submitted in January 2015 as a formal SIP revision and has not been approved by EPA at the time this SIP revision was completed. A progress report update is included with this SIP revision in Section 9. Future progress reports are due by January 31, 2025, July 31, 2033, and every 10 years thereafter.

1.4.2 North Dakota State Authority

The purpose of this submittal is to address the State Implementation Plan requirements for the State of North Dakota found in Paragraph 40 CFR 51.308, Regional Haze Program Requirements, of 40 CFR Part 51 Subpart P - Protection of Visibility.

The North Dakota Department Environmental Quality (the Department or NDDEQ), the agency designated to administer and coordinate a statewide program of air pollution control, has general legal authority under North Dakota Century Code Sections 23.1-01-06 and 28-32-02 to adopt and enforce rules for visibility protection including regional haze visibility impairment.

The Department adopted rules to implement Sections 40 CFR 51. 300 - 307 (North Dakota Administrative Code [NDAC] Chapter 33.1-15-19 Visibility Protection) and to implement Section 40 CFR 51.308 (NDAC Chapter 33.1-15-25 Regional Haze Requirements).

It is the legal opinion of the North Dakota Attorney General that the State Implementation Plan (SIP) is legal, valid and the Air Pollution Control Permit to Construct for the BART source (Coal Creek Station) included within the SIP in Appendix F has the force and effect of law. A copy of the Attorney General opinion is contained in Appendix G.

2 North Dakota Regional Haze SIP Development Process

In development of this proposed RH SIP revision, the Department relied on a significant amount of work completed through collaboration with the Western Regional Air Partnership (WRAP) regional planning organization. 40 CFR §51.308(f)(2)(iii) and 40 CFR §51.308(d)(3)(iii) both state, in part, *"The State must document the technical basis,...The State may meet this requirement by relying on technical analyses developed by a regional planning process and approved by all State participants."* The technical analysis and support provided by WRAP are detailed in Section 2.2, Section 7, and Appendix C. This information is also publicly available through the WRAP website²⁶ and the Technical Support System website²⁷.

In addition, the Department independently evaluated sources and sectors of significance in North Dakota following the requirements of CAA Section 169A, 40 CFR §51.308(d)(1), and 40 CFR §51.308(f)(2).

²⁶ <https://www.wrapair2.org/>

²⁷ <https://views.cira.colostate.edu/tssv2/>

Evaluations were performed to determine potential emission reduction measures which may be necessary when identifying what is required to show reasonable progress. Section 4.1.7 contains the cumulative emissions reductions identified in consideration of the four factors. Section 5.2 contains an overview of the long-term strategy review process for each source evaluated.²⁸ Section 6 contains the Department's discussion and determination of the reasonable progress goals set for this planning period. The emission reduction measures evaluations contain four factors which must be taken into consideration. These factors are costs of compliance, the time necessary for compliance, the energy and non-air quality environmental impacts of compliance, and the remaining useful life of any potentially affected anthropogenic source of visibility impairment.²⁹

In determining reasonable progress, North Dakota can consider visibility and projected visibility improvements. Utilizing its discretion, the Department chose to consider visibility and the modeled visibility improvements projected to result from the implementation of any emission reduction measures prior to finalizing any measure for inclusion in the long-term strategy.

The Department identified three potential emission reduction strategies from the four-factor analyses to determine the resulting modeled visibility improvement. The results of the modeling evaluation were used by the Department to inform its decision as to which potential emissions reduction measures are appropriate and necessary to include in the long-term strategy. In other words, the proposed reasonable progress goal for each Class I area was determined by North Dakota based on its evaluation of three unique potential long-term strategies. Upon consideration of the three long-term strategies and associated modeled visibility conditions, the Department determined that the long-term strategy necessary to meet the statutory reasonable progress requirement was the baseline 2028 strategy. North Dakota's long-term strategy and the reasonable progress goals comply with the requirement of 40 CFR §51.308(f)(3)(i) to provide for an improvement on the most impaired days since the baseline period and ensure no degradation in visibility for the clearest days since the baseline period. Section 3.1, Section 3.2.7, and Section 6.1 contain the information demonstrating North Dakota's Class I areas are meeting the reasonable progress requirements.

Of note, extensive issues in the modeling were experienced during the planning process, leading to a significant delay in receipt of this vital information. Modeling information is vital to the RHR as it is the only tool available to determine what future visibility impairment in the CIAs is projected to be, what impact additional controls may have on CIA visibility projections, and to determine the impact individual states and sectors (e.g., coal fired EGUs) have on visibility in the CIAs. Since the RHR is focused on improving visibility in CIAs, North Dakota was obligated to wait for this information to become available to perform a thorough analysis. Once available, North Dakota performed a detailed review and incorporated the applicable results into this SIP revision.

The modeling contractor, Ramboll U.S. Contracting – Environment and Health unit, provided a memo and letter to WRAP on February 8, 2021, detailing and explaining the litany of reasons which led to the delays

²⁸ Appendix A and Appendix B contain the information used in support of the statements included in Section 5.2.

²⁹ CAA Section 169A(g), 40 CFR §51.308(d)(1), and 40 CFR §51.308(f)(2)

in completing the regional haze modeling. Mainly, the delays were attributed to: COVID-19, delays in data processing decisions at EPA, various bugs in the model platform, wildfires causing power outages in both 2019 and 2020, errors and double counting in emissions inventories, and many other issues. Complete details and a copy of this information can be found in Appendix C. For context, the 2018–2019 WRAP board approved workplan projected the regional haze modeling to be completed in Quarter 2 of 2020, with results available for state use in Quarter 3 of 2020.³⁰ The modeling was completed and made available for state use in March 2021. On April 1, 2021, a results meeting was held to present the final data needed for incorporation into the SIP revision.³¹ North Dakota has been actively working with the data to interpret and incorporate the information into this SIP revision. North Dakota has provided this information to further explain the situation to interested parties and explain why North Dakota missed the July 31, 2021, deadline.

2.1 §51.308(i) – Consultation with Federal Land Managers (FLM), Neighboring States, and Tribes

All significant communications between NDDEQ, EPA, FLMs, Tribal partners, and other states in preparation of the draft RH SIP revision have been included in Appendix E. All formal communications and requests for input between NDDEQ, EPA, FLMs, Tribal partners, and other states has been included in Appendix D.

2.1.1 Federal Land Managers

Per 40 CFR §51.308(f)(2)(ii), §51.308(i)(2), and §51.308(i)(4), North Dakota consulted with FLMs for all in-state CIAs and affected out-of-state CIAs on an ongoing basis through WRAP and separate calls. The National Park Service (NPS) requested that North Dakota evaluate nine sources for reasonable progress. The nine sources requested were included in North Dakota’s four factor evaluations, see Section 5.2, Appendix A, and Appendix B.

The Department met with the NPS and USFS via Microsoft Teams to discuss impairment in CIAs and provide an overview of North Dakota’s regional haze situation and plan in during the SIP Revision for Round 2 of regional haze (PowerPoint³²). The Department met via video conference with the National Park Service on November 6, 2020, and on December 15, 2020. The Department met via video conference with the United States Forest Service on November 23, 2020.

Once an initial draft of North Dakota’s RH SIP revision was completed, the Department held an early engagement consultation period for the FLMs from September 20, 2021, through November 19, 2021. In addition to the early consultation, a video conference meeting was held on November 10, 2021.³³ The objective of the meeting was to discuss the draft RH SIP revision and to receive feedback from the FLMs. Attendees included the NDDEQ, National Park Service, U.S. Forest Service, and EPA Region 8. This engagement period provided the stakeholders with an early opportunity to review and comment on North

³⁰ Available at: <https://www.wrapair2.org/pdf/2018-2019%20WRAP%20Workplan%20update%20Board%20Approved%20April.3.2019.pdf> (Last visited June 1, 2021)

³¹ Available at: <https://www.wrapair2.org/RHPWG.aspx>. See April 1, 2021 – Meeting 8. (Last visited June 1, 2021)

³² PowerPoint can be found in Appendix E, pages E.2-63–94

³³ Consultation slides can be found in Appendix D.2.a, page D.2.a-119.

Dakota's initial draft RH SIP revision. Feedback was received from the National Parks Service on November 19, 2021, and from the U.S. Forest Service on November 17, 2021.

Feedback was received from the FLMs on the following topics: correlation between park visitation and visibility impairment; cost thresholds for additional source controls; the uniform rate of progress toward natural visibility conditions; the impact to visibility conditions when considering the four statutory factors; visibility trends and impacts to out of state Class I areas; costs in the four factor evaluations; feasibility of selective catalytic reduction on North Dakota lignite sources; North Dakota upstream oil and gas industry; and increased future prescribed fire emissions. The FLM comments have been included in Appendix D.2.a and D.2.b. The Department's response can be found in Appendix D.2.c.

As required by §51.308(i)(4), the Department will continue to coordinate and consult the FLMs during the development of future progress reports and RH SIP revisions, as well as during the implementation of programs having the potential to contribute to visibility impairment in CIAs. The progress reports and RH SIP revisions are to occur at five-year intervals, see Section 1.4.1. This consultation process shall provide on-going and timely opportunities to address the status of the control programs identified in this RH SIP revision, the development of future assessments of sources and impacts, and the development of additional control programs. The consultation will include the status of the following specific implementation items:

1. Implementation of emissions strategies identified in the RH SIP revision as contributing to achieving improvement on the most impaired days.
2. Summary of major new permits issued.
3. Status of State actions to meet commitments for completing any future assessments or rulemaking on sources identified as likely contributors to visibility impairment, but not directly addressed in the most recent RH SIP revision.
4. Any changes to the monitoring strategy or monitoring stations status that may affect tracking of reasonable progress.
5. Work underway for preparing the progress reports and periodic RH SIP revisions.
6. Summary of topic discussions (meetings, emails, other records) covered in ongoing communication between the State and FLMs regarding implementation of the visibility program.

2.1.2 Minnesota

Per 40 CFR §51.308(f)(2)(ii), the Department consulted with Minnesota. On March 22, 2021, the Department met with Minnesota to discuss the status of the proposed SIP revisions for North Dakota and Minnesota. At the time of the discussion, both Minnesota and North Dakota were waiting for the respective regional planning organizations to complete photochemical grid modeling. In June 2021, the Department first formally requested feedback regarding visibility impairment to/from Minnesota.³⁴ The Department again provided an opportunity for Minnesota to comment during both FLM consultation³⁵

³⁴ Appendix E.2-106 and E.2-107

³⁵ Appendix D.1-9 and D.1-10

and the public comment period³⁶. Minnesota did not identify any sources or areas of concern regarding visibility impacts from North Dakota.³⁷

2.1.3 Montana

Per 40 CFR §51.308(f)(2)(ii), the Department consulted with Montana. The Department also participated in routine engagement with Montana during development of this SIP revision. The first meeting was held on June 12, 2019, where source selection and international impacts were discussed. On June 2, 2020, the Department met again with Montana to review weighted emissions potential and area of influence modeling results. Starting in October of 2020, Montana and North Dakota met approximately every two weeks to discuss the utilization of WRAP products and SIP development. Engagement also happened through WRAP regional haze workgroup meetings. In June 2021, the Department first formally requested feedback regarding visibility impairment to/from Montana.³⁸ The Department again provided an opportunity for Montana to comment during both FLM consultation³⁹ and the public comment period⁴⁰. Montana did not identify any sources or areas of concern regarding visibility impacts from North Dakota.

2.1.4 South Dakota

Per 40 CFR §51.308(f)(2)(ii), the Department consulted with South Dakota. The Department also participated in routine engagement with South Dakota during development of this SIP revision. Engagement happened primarily through WRAP regional haze workgroup meetings. North Dakota and South Dakota also met directly on October 6, 2020, to discuss sources, controls, and general SIP development. In June 2021, the Department first formally requested feedback regarding visibility impairment to/from South Dakota.⁴¹ The Department again provided an opportunity for South Dakota to comment during both FLM consultation⁴² and the public comment period⁴³. South Dakota did not identify any sources or areas of concern regarding visibility impacts from North Dakota.

2.1.5 Other States

The Department participated in routine engagement with EPA Region 8 states and all WRAP states during development of this SIP revision. Engagement happened primarily through WRAP regional haze workgroup meetings. No states identified any sources or areas of concern regarding visibility impacts from North Dakota.

2.1.6 Collaboration with Tribes

The Department will also work to consult its Tribal partners in North Dakota during the consultation period required under 40 CFR 51.308(i)(2). A copy of the draft RH SIP revision to: Mandan, Hidatsa & Arikara Nation, Standing Rock Sioux Tribe, Sisseton Wahpeton Oyate, Turtle Mountain Tribe, and Spirit Lake Tribe,

³⁶ Appendix D.3.a-13.

³⁷ In a June 23, 2022, email from Minnesota to the Department, Minnesota stated that it is not making any formal ask regarding sources.

³⁸ Appendix E.2-103 and E.2-104

³⁹ Appendix D.1-11 and D.1-12

⁴⁰ Appendix D.3.a-14.

⁴¹ Appendix E.2-105

⁴² Appendix D.1-13 and D.1-14

⁴³ Appendix D.3.a-22.

inviting them to consult with the Department on the SIP Revision. No comments were received from North Dakota's Tribal partners during the early engagement consultation period held from September 20, 2021, through November 19, 2021. No comments were received from North Dakota's Tribal partners during formal public comment period which ended on June 1, 2022.

2.2 Western Regional Air Partnership (WRAP) Engagement

WRAP is a voluntary partnership of states, tribes, federal land managers, local air agencies and the United States EPA. The purpose of the partnership is to understand current and evolving regional air quality issues in the western United States. The WRAP assists state air agencies in preparing plans to meet the requirements of the federal RHR. The WRAP region encompasses the 15-state area of Alaska, Arizona, California, Colorado, Hawaii, Idaho, Montana, Nevada, New Mexico, North Dakota, Oregon, South Dakota, Utah, Washington, and Wyoming.

The Department participates in WRAP planning to assist with the preparation of North Dakota's regional haze SIP revision. The WRAP Regional Haze Planning Work Group provided ample support for the development of various elements required for the regional haze SIP revisions, such as:

- Current and future emissions inventories, including growth projection methodologies by source categories
- Development of a transparent and complete monitoring data metric for planning and model projection purposes
- Database management, including the TSSv2 database detailed in Section 2.2.4
- 4-factor analysis for control measures
- Regional photochemical modeling
- Assessment of "unknowns" and uncertain categories, including natural conditions, international emissions, fire and dust emission, etc.
- Development of Regional Haze SIP revision content and progress report template
- Development of a control strategies menu for major western state sources

Full details of the support provided were documented and can be found on the Regional Haze Planning Work Group webpage: <https://www.wrapair2.org/RHPWG.aspx>.

In addition to the WRAP planning workgroup, the Department participated in various other WRAP workgroups which developed materials in support of the WRAP State's regional haze SIP revisions. These include the Oil and Gas Work Group, Regional Technical Operations Work Group, Fire and Smoke Group, and the Tribal Data Work Group. Each of these work groups are summarized in Sections 2.2.1 through 2.2.4.

2.2.1 Oil and Gas Work Group

The overview of the Oil and Gas Work Group on the WRAP webpage (<https://www.wrapair2.org/ogwg.aspx>) states:

"The oil and gas sector is rapidly changing due to variations in commodity prices, technology innovations, and emerging regulatory programs. The Intermountain Region is especially impacted by exploration and

production emissions from the oil and gas industry, and the West more broadly by emissions from the transport and use of those fuels. National Ambient Air Quality Standards (NAAQS) exceedances during winter in production regions of Utah and Wyoming have demonstrated localized effects, while the contributions from exploration and production in the wider region on summer ozone is still being assessed. In addition, this sector must be considered for Regional Haze planning. Studies point to improvements in the emissions inventory as being one of the most needed products to improve performance of the air quality models and will be a key focus of this work group.”

Development of a more accurate emissions inventory for upstream North Dakota oil and gas operations was the most significant undertaking by North Dakota for this work group. North Dakota supported this initiative by providing updated information on current production. North Dakota also provided future forecasted production using North Dakota Industrial Commission projections. North Dakota also assisted in the development of the revised emissions inventory through collection of survey data from operators in the state of North Dakota. The survey results supported the development of the work products produced by the Oil and Gas Work Group.⁴⁴

North Dakota’s oil and gas sector is discussed in Section 5.2.11.

2.2.2 Regional Technical Operations Work Group

The Regional Technical Operations Work Group compiled emissions data from the various sectors and performed the modeling used to support the Department’s long term strategy and selection of RPGs in Section 6. These modeling results were also used to support the visibility analysis in Section 3.

The Regional Technical Operations Work Group webpage (<https://www.wrapair2.org/rtowg.aspx>) lists the following bullet points as the overview of the group:

- *“Regional analyses in support of planning activities related to emissions and modeling for regional haze, ozone, PM, and other indicators.*
- *Evaluation of background and regional transport, international transport, sensitivity and other analyses of emissions data focused on the western U.S.*
- *Perform and leverage modeling, data analysis, and contribution assessment studies.*
- *Investigation of “background ozone” impacts to western U.S. locations.*
- *Coordination and collaboration with other WRAP member-sponsored regional air quality modeling groups including Intermountain West Data Warehouse (IWDW), NW-AirQuest, EPA-Office of Air Quality Planning and Standards, Bay Area Air Quality Management District, and other state and local agencies performing regional ozone modeling.*
- *Provide guidance on more complete and uniform model performance evaluations (MPes).*
- *Develop and implement a protocol to use the IWDW- Western Air Quality Study capabilities as the WRAP Regional Technical Center.”*

⁴⁴ Available at: https://www.wrapair2.org/pdf/WRAP_OGWG_Report_Baseline_17Sep2019.pdf (Last visited February 23, 2021)

2.2.3 Fire and Smoke Group

Complete details of the Fire and Smoke Group (FSWG) can be found on the WRAP webpage (<https://www.wrapair2.org/fswg.aspx>). A summary of the Fire and Smoke Group (FSWG) is as follows:

The FSWG focused on analysis and planning activities related to IMPROVE activity data to support emissions inventories for fire and smoke emissions. Both natural, unplanned wildfires and planned, prescribed fire are important air pollution sources in the western United States.

The FSWG developed the emissions inventories used to in the modeling to support the regional haze planning efforts. Fire impacts on North Dakota are discussed in Section 3.3 and emissions are addressed in Section 4.8.

2.2.4 Technical Information and Data on TSSv2

WRAP partners help operate and manage the Technical Support System (TSS). The TSS provides air quality data related to regional haze to agency planners, land managers, and the public. The TSS offers interactive displays showing technical data and measurements for the WRAP states, such as:

- the location of CIAs and IMPROVE monitor sites;
- visibility conditions at CIAs over time (i.e., how much light is being scattered and thus preventing people from seeing clearly over long distances and time);
- the number of visibility-impairing particles in the air at CIAs;
- the quantity of pollutants that contribute to visibility impairment for each source in each state;
- results of computer modeling showing how emissions travel long distances from an anthropogenic or natural source, how they contribute to the formation of visibility impairing particles, and how visibility is impaired happens as a result;
- results of computer modeling showing how air pollution control measures might affect visibility conditions at CIAs.

The technical data on the WRAP TSSv2 was used significantly by North Dakota for many of the figures, graphs, and tables used to support North Dakota's regional haze SIP revision. North Dakota utilized the technical data in considering and developing Section 3: North Dakota Visibility Analysis, Section 4: Emissions Inventory, Section 5: §51.308(f)(2) – Long Term Strategy for North Dakota, Section 6: §51.308(f)(3) – Modeling of Long-Term Strategy to Set Reasonable Progress Goals, Section 7: Overview of WRAP Modeling Scenarios, and Section 9: §51.308(g) – Five-Year Progress Report.

The WRAP TSS version 2 can be found at: <https://views.cira.colostate.edu/tssv2/>.

2.3 Coordinated Emission Management Strategies

Due to the insignificant impacts from North Dakota sources on out of state CIAs, there was no need for any coordinated emission management strategies. North Dakota notes oil and gas production on the Fort Berthold Indian Reservation accounts for at least 20% of the total oil production from the entire state of North Dakota. Should there be a need in the future to reduce visibility impacts from the oil and gas sector, a coordinated approach between EPA, the MHA Nation, and the Department would be necessary.

2.4 North Dakota sources identified by downwind states that are reasonably anticipated to impact CIAs

Due to the insignificant impacts from North Dakota sources on out of state CIAs, no sources were identified as reasonably anticipated to impact out of state CIAs. WRAP produced Weighted Emissions Potential (WEP) and Area of Influence (AOI) products (Section 7.5) which were used as supplemental information to help determine potential impacts from North Dakota sources to out of state CIAs and determine impacts to North Dakota CIAs from out of state sources. The products were used qualitatively to assist the Department in selection of the appropriate source categories that have the highest potential to contribute to visibility impairment from NO_x and SO₂. A summary of these results is included in Appendix C.

2.5 Public Participation and Review Process

The Public Hearing Record is included in Appendix D.3.

2.5.1 Public Comment Period and Hearing Information

NDDEQ held a public comment period and public hearing for this proposed RH SIP revision at the following time and location:

The public comment period ends on June 1, 2022. Direct comments, in writing, to the North Dakota Department of Environmental Quality, Division of Air Quality, 4201 Normandy Street, Bismarck North Dakota, 58503 or AirQuality@nd.gov, Re: Regional Haze SIP Revision. Please note that, to be considered, comments submitted by email must be sent to the email address listed. Comments must be received by 11:59 PM central time on the last day of the public comment period to be considered in the final determination.

A public hearing to address the proposed changes to the SIP revision will be held at 9:00am CDT on May 31, 2022, at 4201 Normandy Street, Bismarck North Dakota, 58503.

An electronic version of this proposed Regional Haze SIP Revision and Appendices can be found at the Departments Website: <https://www.deq.nd.gov/AQ/planning/RegHaze.aspx>.

2.5.2 Comments Received during Public Comment Period/Hearing

Comments received during the public comment period have been included in Appendix D.6.

2.5.3 Response to Public Comments

NDDEQ's responses to public comments have been included in Appendix D.5.

2.6 Review and Commitment to Further Planning

Public comments, including those from federal agency staff, are provided on NDDEQ's regional haze webpage and in Appendix D. The final RH SIP revision incorporates public comments and the NDDEQ's responses, as required per 40 CFR 51.308(i)(3).

2.7 Revisions to the State Implementation Plan Post Public Comment

NDDEQ has updated the Coal Creek Station NO_x BART analysis and determination based on EPA Comments 27 through 33. An explanation of how EPA comments were incorporated has been provided in Appendix D.5. No additional significant revisions to the State Implementation Plan were warranted upon review and consideration of the comment received.

3 North Dakota Visibility Analysis

To assess haze most effectively in mandatory CIAs, the causes of haze must first be determined. This section summarizes the causes of haze in North Dakota CIAs, details the progress made since the baseline period, breaks down the Natural and International impairment contributions, breaks down the US anthropogenic contributions by state and sector, and discusses the impacts of U.S. wildfires on North Dakota visibility. This section satisfies the requirements of 40 CFR 51.308(f)(1) and 40 CFR 51.308(d)(2).

3.1 Visibility Summary

3.1.1 Most Impaired Days Visibility Summary

Visibility on the MIDs at LWA and TRNP is adversely impacted by many different sources, most of which are outside of North Dakota's ability to regulate. Figure 14 and Figure 15 display a graphical breakdown of the contributors to visibility impairment. Table 3 and Table 4 display the numerical percentages associated with Figure 14 and Figure 15. As displayed in these figures and tables, only 20% of the total impairment at LWA and 13% of the total impairment at TRNP is from sources within North Dakota. The remaining impairment on the MIDs comes from international, natural, and US sources outside of North Dakota.

The 13 different sources contributing to visibility impairment are shown in Figure 14 and Figure 15. Some of the source values are very small and therefore do not show up significantly in the figures. The sources contributing to visibility impairment include North Dakota EGU (ND EGU), North Dakota Oil and Gas (ND OilGas⁴⁵), North Dakota Mobile (ND Mobile), North Dakota non EGU (ND NonEGU), Remaining North Dakota (ND RemainAnthro), Boundary Conditions from US sources (BCUS), all other US Anthro (Remaining US), International Anthropogenic (Int_Anthro), Canadian-Mexican Fire (CanMexFire), Natural, US prescribed wildland fires (US_RxWildland Fire), US wildfires (US_Wildfire), and Rayleigh. The species contributing to visibility impairment include ammonium nitrate, ammonium sulfate, coarse mass, elemental carbon, organic mass, sea salt, and soil. These are displayed in Table 3 and Table 4. The sources make up the 2028 column displayed in Figure 14 and Figure 15.

Also shown in Figure 14 and Figure 15 are the baseline visibility conditions from 2000-2004 (Baseline '00-'04), IMPROVE 5-yr rolling average trendline, unadjusted uniform rate of progress (Glidepath), and adjusted uniform rate of progress (Adjusted Glidepath). For the North Dakota "ND" sources, the visibility impairment species only includes ammonium nitrate and ammonium sulfate, the species of most interest from anthropogenic sources. All ND impairment from coarse mass, elemental carbon, organic mass, sea salt, and soil are combined with the Remaining US category.⁴⁶ This helps show the most controllable portion of visibility impairment from North Dakota anthropogenic sources.

⁴⁵ The oil and gas sector consists of area sources, point sources, and tribal oil and gas operations. Oil and gas area sources, which includes tribal operations, are comprised of over 15,000 individual wells spread across roughly 8,000 locations.

⁴⁶ Ammonium nitrate and ammonium sulfate were the only species tracked when determining the US State and sector contributions to light extinction. See Section 7.4 for details.

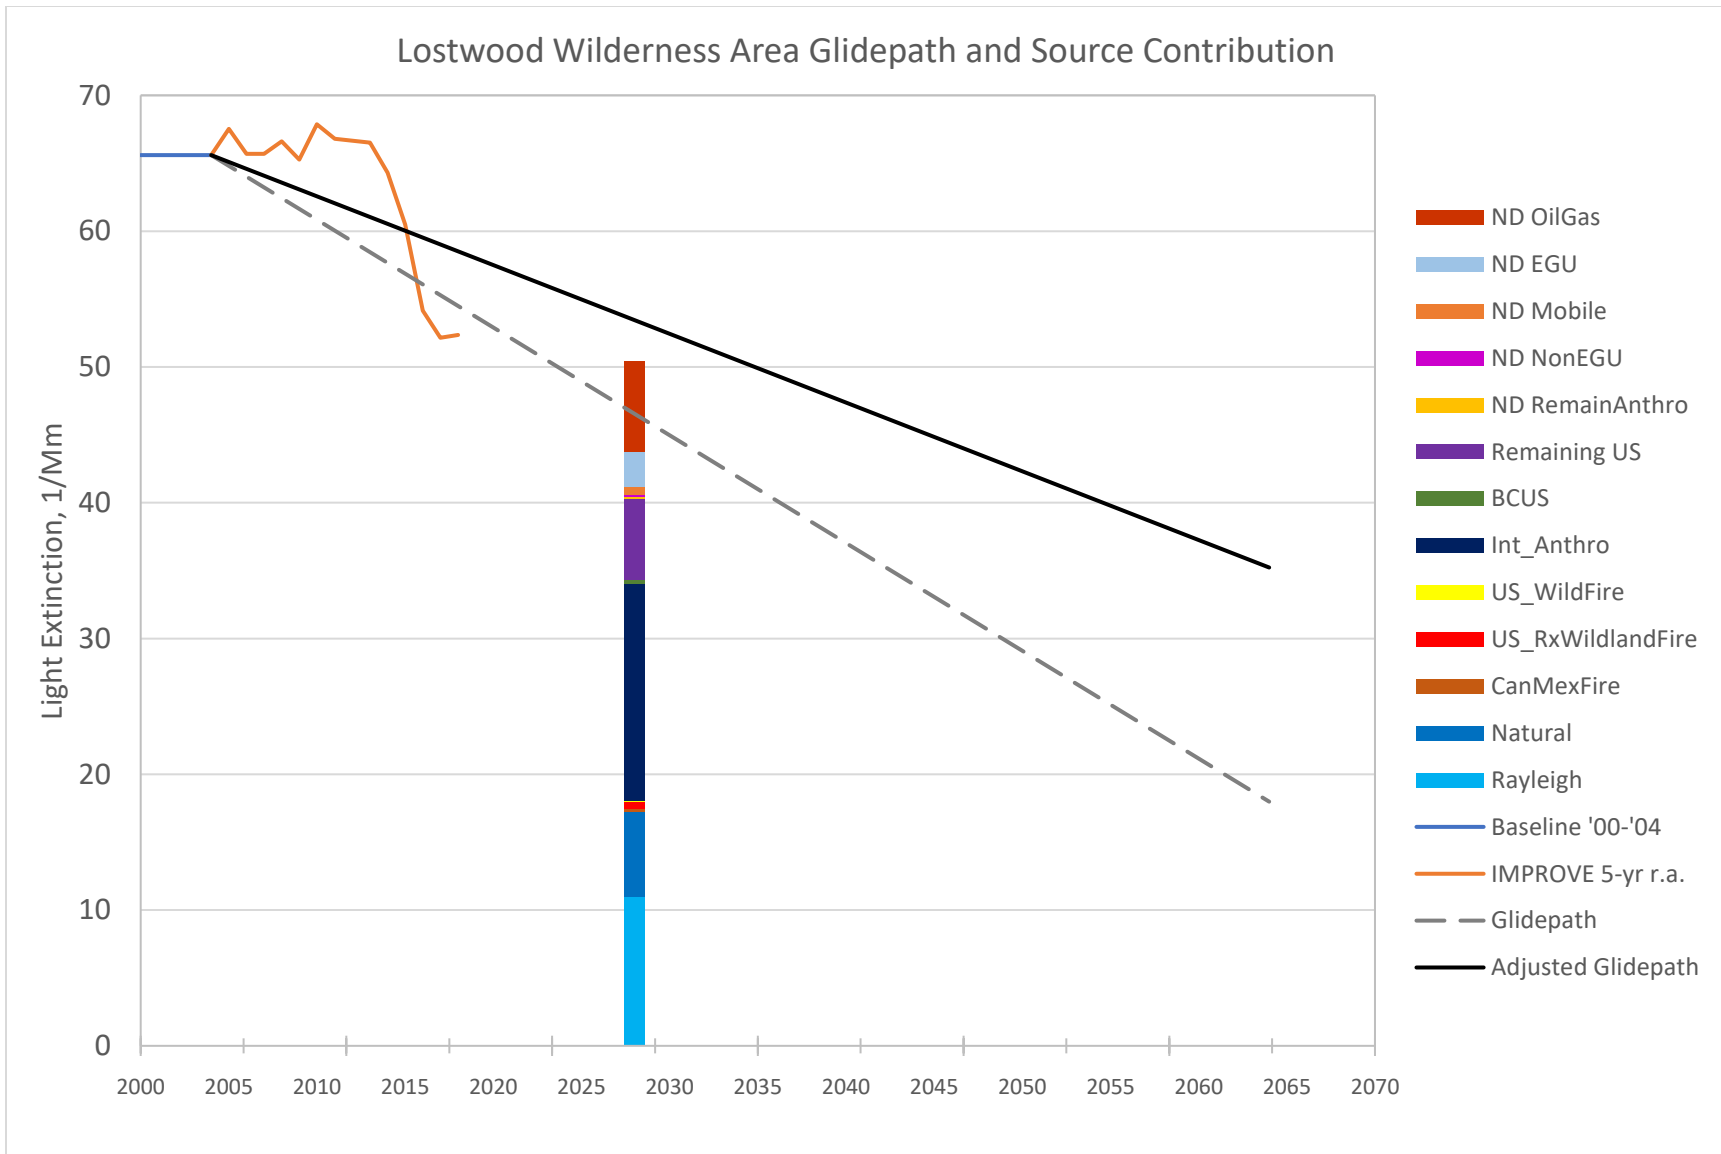

Figure 14: LWA contributors to visibility impairment, overall progress since baseline period, and 2028 projection

Table 3: LWA percent breakdown of 2028 projected visibility impairment

Sector	Ammonium Nitrate	Ammonium Sulfate	Coarse Mass	Elemental Carbon	Organic Mass	Sea Salt	Soil	Grand Total
ND EGU	1%	4%	--	--	--	--	--	5%
ND OilGas	8%	6%	--	--	--	--	--	13%
ND Mobile	1%	0%	--	--	--	--	--	1%
ND NonEGU	0%	0%	--	--	--	--	--	0%
ND RemainAnthro	0%	0%	--	--	--	--	--	0%
BCUS	0%	0%	--	--	--	--	--	1%
Remaining US	4%	2%	2%	1%	2%	0%	0%	12%
Int_Anthro	15%	13%	1%	1%	1%	0%	0%	32%
CanMexFire	0%	0%	0%	0%	0%	0%	0%	1%
Natural	5%	4%	1%	0%	2%	0%	0%	12%
US_RxWildlandFire	0%	0%	0%	0%	0%	0%	0%	1%
US_WildFire	0%	0%	0%	0%	0%	0%	0%	0%
Grand Total (non-Rayleigh)	35%	30%	4%	3%	6%	0%	0%	78%
Rayleigh								22%
Sources Plus Rayleigh								100%

--", speciated breakdown not available, included with "Remaining US" sector

Table 3 lists the percent breakdown of projected visibility impairment for LWA on the MIDs. Table 3 shows that Int_Anthro is the largest contributor to visibility impairment and accounts for 32% of the overall light extinction, 28% of which is from ammonium nitrate and ammonium sulfate. The largest North Dakota contributor is the oil and gas sector at 13% of the overall impairment, 8% from ammonium nitrates and 6% from ammonium sulfates. The next largest North Dakota sector is EGU at 5%, 4% from ammonium sulfates and 1% from ammonium nitrates. Collectively, these sources contribute only 18% of the ammonium nitrate and sulfate light extinction projection on the MIDs. Natural sources account for 12% of the total light extinction and Rayleigh light scattering contributes to 22% of the total light extinction.

Figure 15: TRNP contributors to visibility impairment, overall progress since baseline period, and 2028 projection

Table 4: TRNP percent breakdown of 2028 projected visibility impairment

Sector	Ammonium Nitrate	Ammonium Sulfate	Coarse Mass	Elemental Carbon	Organic Mass	Sea Salt	Soil	Grand Total
ND EGU	0%	2%	--	--	--	--	--	2%
ND OilGas	5%	4%	--	--	--	--	--	9%
ND Mobile	1%	0%	--	--	--	--	--	1%
ND NonEGU	0%	0%	--	--	--	--	--	0%
ND RemainAnthro	0%	0%	--	--	--	--	--	0%
BCUS	0%	1%	--	--	--	--	--	1%
Remaining US	4%	3%	3%	1%	3%	0%	0%	14%
Int_Anthro	11%	17%	1%	1%	1%	0%	0%	31%
CanMexFire	0%	0%	0%	0%	0%	0%	0%	0%
Natural	4%	6%	1%	0%	2%	0%	0%	13%
US_RxWildlandFire	0%	0%	0%	0%	0%	0%	0%	1%
US_WildFire	0%	0%	0%	0%	0%	0%	0%	0%
Grand Total (non-Rayleigh)	26%	33%	5%	2%	6%	0%	1%	73%
Rayleigh								27%
Sources Plus Rayleigh								100%

--", speciated breakdown not available, included with "Remaining US" sector

Table 4 lists the percent breakdown of projected visibility impairment for TRNP on the MIDs. Table 4 shows that Int_Anthro is the largest contributor and accounts for 31% of the overall light extinction, 28% of which is from ammonium nitrate and ammonium sulfate. The largest North Dakota contributor to visibility impairment is the oil and gas sector at 9% of the overall impairment, 5% from ammonium nitrates and 4% from ammonium sulfates. The next largest North Dakota sector is EGU at 2%, 1.7% from ammonium sulfates and 0.4% from ammonium nitrates.⁴⁷ Collectively, these sources contribute only 11% of the ammonium nitrate and sulfate light extinction projection on the MIDs. Natural sources account for 13% of the total light extinction and Rayleigh light scattering contributes to 27% of the total light extinction.

⁴⁷ One additional significant figure displayed for informational purposes.

Combined impairment at LWA from sources outside of North Dakota's control accounts for roughly 80% of the total light extinction.⁴⁸ The remaining 20% of the total light extinction (ammonium nitrate and ammonium sulfate) is from North Dakota sources, spread mainly between ND OilGas and ND EGU.

Combined impairment at TRNP from sources outside of North Dakota's control accounts for roughly 87% of the total light extinction.⁴⁹ The remaining 13% of the total light extinction (ammonium nitrate and ammonium sulfate) is from North Dakota sources, mainly attributable to ND OilGas.

The supporting details for Figure 14, Figure 15, Table 3, and Table 4 can be found in Sections 3.2, and Appendix C. Additionally, the most significant problem impacting CIA visibility, extreme episodic wildfire events, are discussed in Section 3.3. These events are not shown in Figure 14 nor Figure 15 since these figures remove wildfires by only focusing on the most impaired days as defined in 40 CFR §51.301.

Note: the modeling data displayed in Figure 14, Figure 15, Table 3, Table 4, and Appendix C has been normalized. Meaning the photochemical grid model (PGM) results have been scaled to correlate to the 2028 visibility projections. Where the 2028 visibility projections were determined following EPA recommended methodology.⁵⁰ As stated in the whitepaper *"The projection procedure uses the CAMx RepBase2 and 2028OTBa2 modeling results in a relative fashion to scale the observed IMPROVE concentrations from the 2014-2018 MID to obtain 2028 future year MID concentrations. The model derived scaling factors are called Relative Response Factors (RRFs) and are obtained as the ratio of the CAMx future (2028OTBa2) to current (RepBase2) year modeling results averaged across several days, where the EPA default projection approach uses days from the base year IMPROVE MID."* WRAP determined the overall 2028 visibility projections but did not further breakdown the 2028 projection into source and sector contributions (i.e. international and state sector fractions). The Department performed this normalization in order for the modeled source apportionment results (CAMx) to correlate to the 2028 visibility projections. For North Dakota, this increased the absolute (e.g. inverse megameters of light extinction) contribution to visibility impairment from all categories and has the added benefit of displaying the data consistently throughout the SIP revision. The normalized procedure used by the Department has been documented and is included in Appendix C.

3.1.2 Clearest Days Visibility Summary

Visibility on the clearest days at LWA and TRNP is adversely impacted by many different sources, most of which are outside of North Dakota's ability to regulate. IMPROVE data at LWA and TRNP have shown no degradation in visibility for the clearest days from 2000–2018 (Section 3.2.6.2). The PGM results also show no expected degradation for the clearest days projection in 2028. The 2014–2018 average IMPROVE data for the clearest days at LWA and TRNP shows total species light extinction of 10.2 Mm⁻¹ and 7.1 Mm⁻¹, respectively. The 2028 projected visibility on the clearest days at LWA and TRNP shows total species

⁴⁸ Note: Remaining US sources includes impairment from all US_Anthro species minus ammonium nitrates and ammonium sulfate from the North Dakota sectors.

⁴⁹ Note: Remaining US sources includes impairment from all US_Anthro species minus ammonium nitrates and ammonium sulfate from the North Dakota sectors.

3.2 §51.308(f)(1) Calculations of Baseline, Current, and Natural Visibility Conditions; Progress to Date; and the Uniform Rate of Progress

40 CFR §51.308(f)(1)(i)–(iv) requires states to determine the baseline, current and natural visibility conditions for the 20 percent clearest and 20 percent most impaired days. The 2017 RHR revisions updated the definition of the “most impaired days”, which are now defined as the 20 percent most impaired days based on daily anthropogenic impairment and no longer on the overall 20 percent worst (haziest) days.⁵³ Baseline, current and natural visibility conditions were calculated based on the methodology provided in EPA’s Technical Guidance on Tracking Visibility Progress for the Second Implementation Period of the Regional Haze Program.⁵⁴ The baseline visibility period is the average of the annual deciview index values for the calendar years from 2000–2004, for both the 20 percent MIDs and the 20 percent clearest days. The 20 percent MIDs and the 20 percent clearest days were calculated for the current conditions using the average annual deciview index values for the most recent 5-year period. Natural visibility was calculated by considering only the natural contributions to the annual means on the 20 percent clearest and MIDs from 2000 through 2014.

Table 5 provides reference information for the IMPROVE sites that track visibility conditions at North Dakota’s and neighboring state’s nearby CIAs. IMPROVE sites in western Montana were therefore not included in this section.

Table 5: North Dakota and Nearby State IMPROVE Sites

Site ID	Class I area Name	Representative IMPROVE Site
LOST1	Lostwood National Wildlife Refuge	Lostwood
THRO1	Theodore Roosevelt National Park	Theodore Roosevelt
MELA1	Medicine Lake Wilderness Area (MT)	Medicine Lake
ULBE1	UL Bend Wilderness Area (MT)	U.L. Bend
BADL1	Badlands National Park (SD)	Badlands
WICA1	Wind Cave National Park (SD)	Wind Cave
VOYA2	Voyageurs National Park (MN)	Voyageurs
BOWA1	Boundary Waters Canoe Area Wilderness (MN)	Boundary Waters

3.2.1 §51.308(f)(1)(i) – Baseline visibility for the most impaired and clearest days (2000–2004)

The 5-year average baseline visibility for the clearest and most impaired visibility days for each CIA was calculated using data from the IMPROVE monitoring sites and are shown in Table 6. The calculations were made in accordance with 40 CFR 51.308(f)(1)(i) and EPA’s Technical Guidance document.

⁵³ Final Rule: Protection of Visibility: Amendments to Requirements for State Plans, 82 FR 3101, January 10, 2017.

⁵⁴ Available at: https://www.epa.gov/sites/production/files/2018-12/documents/technical_guidance_tracking_visibility_progress.pdf

Table 6: IMPROVE Sites Clearest and Most Impaired Days Values⁵⁵

Site ID	Class I area	Clearest Days (dv)	Most Impaired Days (dv)
LOST1	Lostwood National Wildlife Refuge	8.2	18.3

BOWA1	Boundary Waters (MN)	6.5	18.4

3.2.2 §51.308(f)(1)(ii) – Natural visibility for the most impaired and clearest days

Natural visibility conditions for each CIA were calculated by estimating the average deciview index considering only natural contributions for the most impaired and clearest days. These calculations were based on IMPROVE monitoring data from 2000–2014 for each site and used EPA’s recommended data analysis techniques. The natural visibility for the clearest days and MIDs is shown in Table 7.

Table 7: Natural Visibility for the Most Impaired and Clearest Days

Site ID	Class I area	Clearest Days (dv)	Most Impaired Days (dv)
LOST1	Lostwood National Wildlife Refuge	2.9	5.9

BOWA1	Boundary Waters (MN)	3.5	9.1

3.2.3 §51.308(f)(1)(iii) – Current (2014–2018) visibility for the most impaired and clearest days

40 CFR 51.308(f)(1)(iii) specifies that current visibility be calculated using the average of the annual deciview index values for the most recent 5-year period, ending with the most recently available data. Table 8 shows the values that were calculated for each CIA on the 20 percent clearest and 20 percent MIDs from 2014–2018.

⁵⁵ Available at: https://www.epa.gov/sites/production/files/2020-06/documents/memo_data_for_regional_haze_technical_addendum.pdf

Table 8: Current (2014–2018) Visibility for the Most Impaired and Clearest Days

Site ID	Class I area	Clearest Days (dv)	Most Impaired Days (dv)

BOWA1	Boundary Waters (MN)	4.5	14.0

3.2.4 §51.308(f)(1)(iv) – Progress to date for the most impaired and clearest days

40 CFR 51.308(f)(1)(iv) requires the demonstration of actual progress made towards the natural visibility condition for the most impaired and clearest days since the baseline period. 40 CFR 51.308(f)(1)(iv) also requires the demonstration of actual progress made during the previous implementation period up to and including the period for calculating current visibility conditions. This progress can be seen by the difference between 1) the average visibility condition in the 5-year baseline, 2) the previous implementation period, and 3) each subsequent 5-year period up to and including the current period, shown in Table 9. Table 9 only displays the previous implementation period as 2008–2012, all 5-year rolling average data since 2004 is addressed in Section 3.2.6.

Table 9: Progress to Date for the Most Impaired and Clearest Days

Site ID	2000-2004 Baseline		2008–2012 Previous Implementation Period		2014–2018 Current

3.2.6 §51.308(f)(1)(vi)(A) – Uniform rate of progress

The uniform rate of progress (URP) glidepath is the rate of progress over time needed to achieve the 2064 visibility end goals. For the 20% MIDs, the goal is to achieve natural visibility conditions by 2064. For the clearest days, the goal is to provide no degradation from the 2000–2004 baseline visibility conditions on the clearest days. This URP analysis is being provided to meet the requirements of §51.308(f)(1)(vi)(A). Section 3.2.7 details the information for the option to adjust the glidepath, as allowed under §51.308(f)(1)(vi)(B). North Dakota is adjusting the glidepath with this SIP revision and Section 3.2.7 contains the data pertinent to reflect this action.

The URP glidepath for each Class 1 area for the MIDs is determined from the five-year baseline visibility condition (Table 6) and the natural visibility condition (Table 7). The five-year baseline visibility condition is the average of the MID from 2000–2004. The natural visibility condition is the average estimated impairment under natural conditions for the MID. The URP glidepath is a linear line drawn from the 2004 baseline visibility starting point to the 2064 natural visibility conditions estimate. For the clearest days, the glidepath is a straight line from the 2000–2004 baseline to 2064.

On June 3, 2020, EPA released a technical addendum which included updated visibility data for the clearest days and the MIDs through 2018.⁵⁷ This data was used for this SIP revision.

3.2.6.1 Most Impaired Data

Figure 17 and Figure 18 show the unadjusted URP glidepath for the MIDs at LWA and TRNP, respectively. This data can be found at: <https://views.cira.colostate.edu/tssv2/Express/VisTools.aspx>. Products 4 and/or 5 on this webpage can be used to recreate the figures used in this section.

Figure 17: LWA Most Impaired Days Progress from 2000–2018

Figure 17 indicates LWA is making continuous progress toward the 2064 end visibility goal. The five-year rolling average IMPROVE data from 2014–2018 indicates LWA is 0.80 deciviews above the URP, however, Figure 17 does not account for visibility impairment from international emissions and wildland prescribed fires. Refer to Section 3.2.7 for graphical representation of these impacts.

⁵⁷ Available at: https://www.epa.gov/sites/production/files/2020-06/documents/memo_data_for_regional_haze_technical_addendum.pdf (Last visited March 1, 2021)

Figure 18: TRNP Most Impaired Days Progress from 2000–2018

Figure 18 indicates TRNP is making continuous progress toward the 2064 visibility goal. The five-year rolling average IMPROVE data from 2014–2018 indicates TRNP is 0.14 deciviews above the URP, however, Figure 18 does not account for visibility impairment from international emissions and wildland prescribed fires. Refer to Section 3.2.7 for graphical representation of these impacts.

3.2.6.2 Clearest Days

Figure 19 and Figure 20 show the glidepath for the 20% clearest days at LWA and TRNP, respectively. This data can be found at: <https://views.cira.colostate.edu/tssv2/Express/VisTools.aspx>. Products 4 and/or 5 on this webpage can be used to recreate the figures used in this section. The data displayed is truncated at 2030 on the x-axis for more clear visual aesthetics.

Figure 19: LWA Clearest Days Progress from 2000–2018

Figure 19 shows that LWA is meeting the requirement of showing no degradation in visibility for the clearest days since the baseline period of 2000–2004. The five-year rolling average IMPROVE data from 2014–2018 indicates LWA is at 7.45 deciviews for the clearest days, below the requirement of 8.19 deciviews.

Figure 20: TRNP Clearest Days Progress from 2000–2018

Figure 20 shows that TRNP is meeting the requirement of showing no degradation in visibility for the clearest days since the baseline period of 2000–2004. The five-year rolling average IMPROVE data from 2014–2018 indicates TRNP is at 5.85 deciviews for the clearest days, below the requirement of 7.76 deciviews.

3.2.7 §51.308(f)(1)(vi)(B)(1) and (2) – North Dakota Adjustments to the uniform rate of progress to account for international impacts and prescribed fire

The 2017 RHR revisions authorize states to make an optional adjustment to the URP glidepath to account for impacts from anthropogenic sources outside of the United States and to account for impacts from wildland prescribed fires.⁵⁸ To calculate the proposed adjustment, the State must add the estimated impact(s) to the natural visibility conditions estimate for the MID at the 2064 end goal.⁵⁹ The natural conditions estimate plus the adjustment for international anthropogenic emissions and wildland prescribed fires provides the adjusted 2064 end goal. This adjustment is critical for North Dakota CIAs since North Dakota shares a boarder with Canada and is heavily impacted by international emissions. North Dakota is also impacted by wildland prescribed fires and is also proposing to take these visibility impairing emissions into consideration. The proposed glidepath adjustment considers both international anthropogenic and wildland prescribed fire contributions.

⁵⁸ 40 CFR 51.308(f)(1)(vi)(B)

⁵⁹ Available at: https://www.epa.gov/sites/production/files/2018-12/documents/technical_guidance_tracking_visibility_progress.pdf, page 17 (Last visited March 1, 2021)

International anthropogenic and wildland prescribed fire combined contributions are based on projected 2028 modeling results normalized to the monitoring data and added to the EPA estimated natural conditions for 2064.

Figure 21 and Figure 22 show the URP glidepath with adjustments for international anthropogenic and wildland prescribed fire (Adjusted Glidepath) for the MIDs at LWA and TRNP, respectively. This data can be found at: <https://views.cira.colostate.edu/tssv2/Express/ModelingTools.aspx>. Product 5 on this webpage can be used to recreate the figures used in this section. WRAP provided adjustment options for two scenarios. One for international, and one for international plus wildland prescribed fire. The adjusted glidepath figures only display the international and wildland prescribed fire results.

Figure 21: LWA Most Impaired Days Progress with Adjusted Glidepath from 2000–2018

Figure 21 indicates LWA is making meaningful progress toward the adjusted 2064 end visibility goal. The five-year rolling average IMPROVE data from 2014–2018 indicates LWA is 0.77 deciviews below the Adjusted Glidepath.

Figure 21 demonstrates the impact international and wildland prescribed fires have on LWA and the importance of using the proposed Adjusted Glidepath. A significant part of the adjustment is due to international sources, not from wildland prescribed fires. When looking strictly at the impacts from international sources, the 2064 end point for LWA is 12.46 deciviews. Meaning, the difference of 0.13 deciviews (12.59 – 12.46) is attributed to the wildland prescribed fires. This is supported by the source category breakdown of visibility impairment discussed in Appendix C.

Figure 22: TRNP Most Impaired Days Progress with Adjusted Glidepath from 2000–2018

Figure 22 indicates TRNP is making meaningful progress toward the adjusted 2064 end visibility goal. The five-year rolling average IMPROVE data from 2014–2018 indicates TRNP is 1.17 deciviews below the Adjusted Glidepath.

Figure 22 demonstrates the impact international and wildland prescribed fires have on TRNP and the importance of using the proposed Adjusted Glidepath. A significant part of the adjustment is due to international sources, not from wildland prescribed fires. When looking strictly at the impacts from international sources, the 2064 end point for TRNP is 11.46 deciviews. Meaning, the difference of 0.09 deciviews (11.55 – 11.46) is attributed to the wildland prescribed fires. This is supported by the source category breakdown of visibility impairment discussed in Appendix C.

3.3 U.S. Wildfire Impacts on North Dakota Visibility

North Dakota does not have large forested areas and therefore, does not have significant wildfire events when compared to other western States such as California, Oregon, and Washington. However, North Dakota's visibility is noticeably impacted by extreme wildfire events emanating from other western States and internationally. For example, 2020 was adversely impacted by record-breaking wildfires on the west

coast^{60,61} causing visibility impairment throughout much of the United States⁶², including North Dakota. As a result of this significantly adverse fire activity, North Dakota experienced long episodes of perceptible visibility impairment from summer through fall of 2020. While 2020 was one of the worst fire years on record, it was not unusual regarding noticeable adverse impacts to North Dakota's visibility in recent years. Many of the Department's air quality press releases over recent years are directly tied to out of state or international wildfire smoke.^{63,64,65} As of the writing of this SIP revision in 2021, North Dakota is also experiencing significant adverse wildfire impacts to health based and visual air quality from out of state fire activity.⁶⁶ Due to the extreme drought conditions throughout much of the western United States, this trend is likely to continue.⁶⁷ The Department typically receives many questions, comments, and/or complaints regarding these issues and has recently started to issue press releases to inform the public of the ongoing situation. Looking forward, the magnitude of impacts from extreme wildfire events are anticipated to continually increase in the coming years. Reducing the size, intensity, duration, and number of wildfires on the west coast or internationally would have the greatest impact on improving visibility at North Dakota's CIAs, especially during the months when the CIAs experience the most visitation (summer and fall).

When the MIDs are compared to the haziest days on a seasonal basis for the years of 2014–2018, it is easy to see that the worst visibility days are the days with wildfire activity. The seasonal data in Figure 23 and Figure 24 is averaged over the years of 2014–2018. If the data from years 2014 and 2016 was removed, as these were not as significant wildfire years, the difference in light extinction on the haziest days versus the MIDs for the summer and fall months would be even more pronounced. The green portion of the bar chart reflects light extinction contributed by organic mass, which is primarily associated with wildfire events. When organic mass impairment is from wildfires, it is typical to see the elemental carbon and coarse mass also increase.

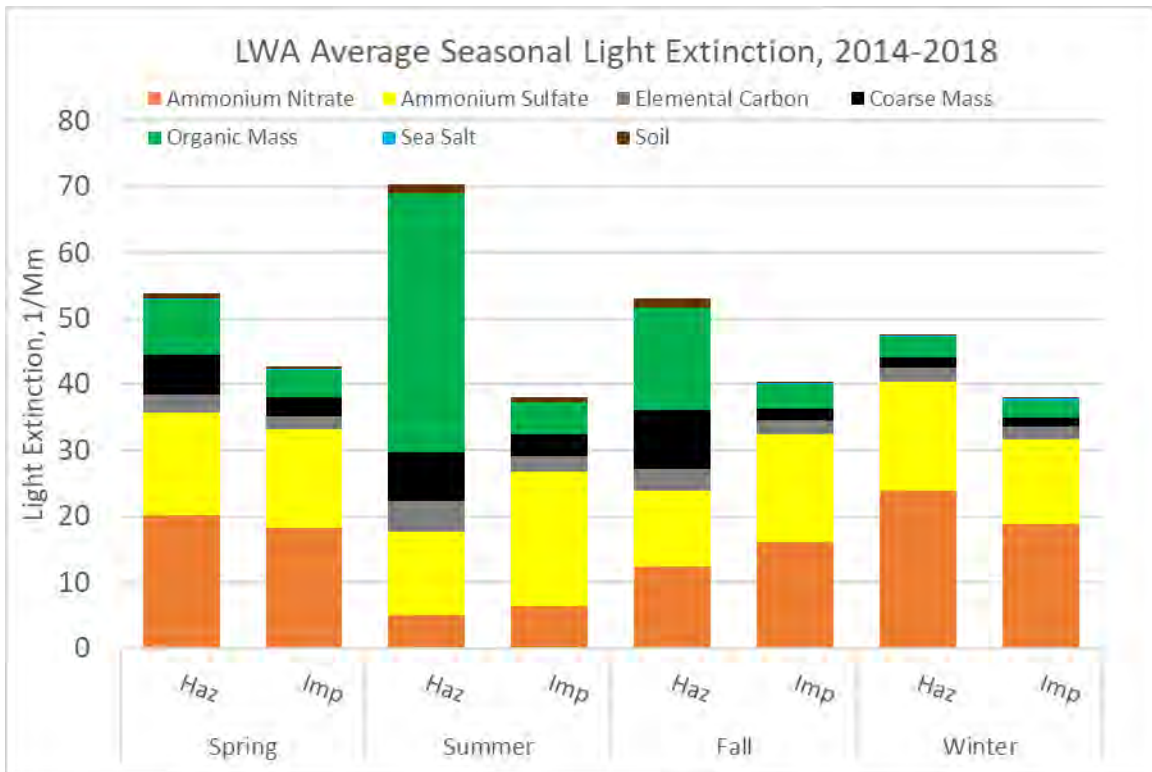

Figure 23: 2014–2018 Average Seasonal Hazyest Days (Haz) and Most Impaired Days (Imp) data for LWA

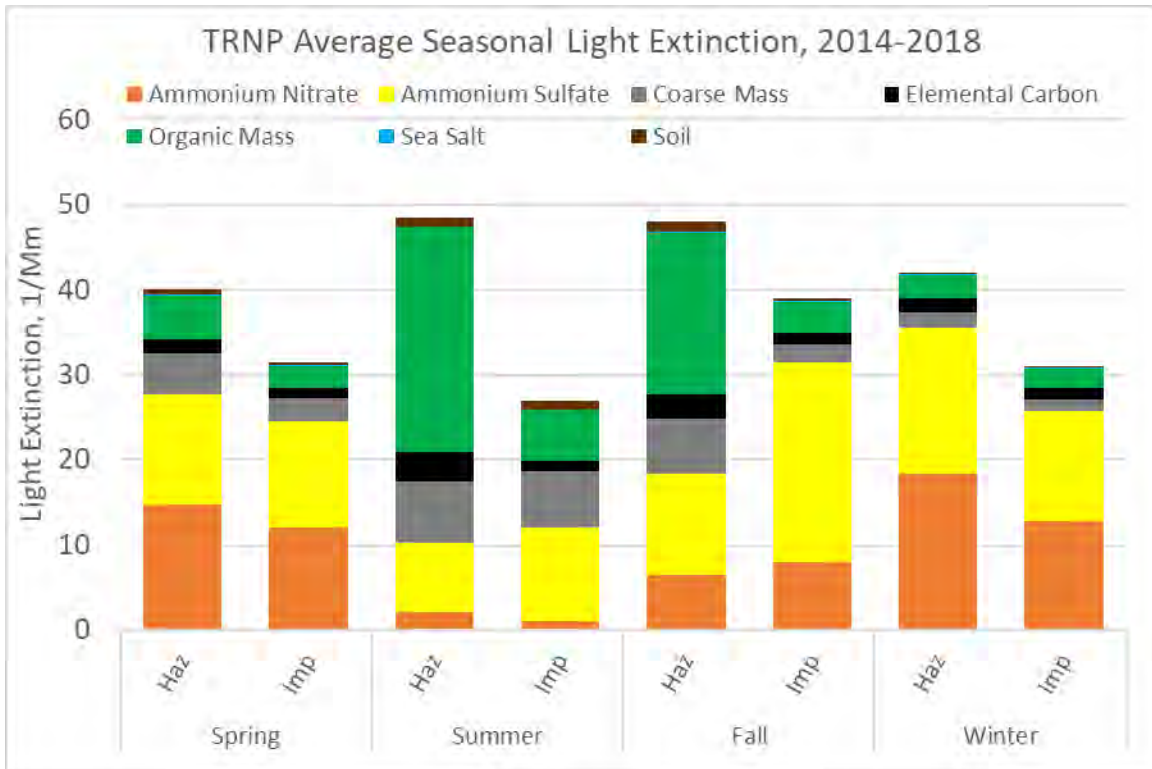

Figure 24: 2014–2018 Average Seasonal Hazyest Days (Haz) and Most Impaired Days (Imp) data for TRNP

There is no distinction between a diminished visual experience caused by anthropogenic sources or natural events⁶⁸, as visual experiences can be impacted by either, or both. However, the largest contributor to visibility impairment in North Dakota CIAs results from wildfires emanating outside of North Dakota. The federal government, applicable state governments, federal land managers, private industry, community groups, nongovernmental organizations, and other stakeholders need to work collaboratively to take on the forest management challenges through implementation of practical and effective measures.^{69,70} These measures will reduce the size, intensity, and duration of extreme wildfires. This is especially needed considering the intense drought much of the western United States is currently experiencing coupled with the projections of increasing extreme wildfire activity in years to come. Emissions inventory estimates resulting from wildfires from the WRAP states have been included in this RH SIP revision to show how significant emissions from these events are, Section 4.8. The emissions inventory estimates are for the 2014 baseline year and a representative fire year (average of 2014–2018 fire estimates).

⁶⁸ Some ‘natural’ events are not truly ‘natural’ in origin, but rather, the result of decades long forest management malpractices and political policies leading to the problem of today.

⁶⁹ Forest Management is More Effective Than Climate Virtue-Signaling, Jason Hayes, October 6, 2020. Available at: <https://www.mackinac.org/forest-management-is-more-effective-than-climate-virtue-signaling> (Last visited March 23, 2021)

4 Emissions Inventory

The RHR requires that emissions inventories (EI) be used to compare past emissions, present emissions, and future projected emissions; necessary to evaluate changes over time and determine if any additional progress is needed to meet the state's RPGs. The emissions inventories include all pollutants that are reasonably anticipated to cause or contribute to visibility impairment in any CIA. The specific sections of the RHR addressing the need for EIs include: §51.308(d)(3)(iii), §51.308(d)(4)(v), §51.308(f)(2)(iii), §51.308(f)(6)(v), and §51.308(g)(4). Each of these sections is subtly different, with the overall purpose being to document the basis for the emissions used in the SIP revision. Emissions are broken down by pollutant and source category.

The source categories used in the inventory analysis include point sources, area and non-point sources, non-road mobile sources, on road mobile sources, natural sources, and international anthropogenic emissions. A list of the modeled source categories is displayed in Table 11.

Table 11: Emissions Categories included in the WRAP modeling.

Sector/Source Category	Sector Code	Type
Agricultural Fire	ag_flaming	Anthropogenic
Agricultural Operations	ag	Anthropogenic
Fugitive Dust (area-source)	afdust	Anthropogenic
Oil & Gas Nonpoint	np_oilgas	Anthropogenic
Rail	rail	Anthropogenic
Remaining Nonpoint	nonpt	Anthropogenic
Residential Wood	rwc	Anthropogenic
Non-road Mobile	nonroad	Anthropogenic
Onroad Mobile	onroad	Anthropogenic
Electricity Generating	ptegu	Anthropogenic
Oil & Gas Point	pt_oilgas	Anthropogenic
Industrial Point	ptnonipm	Anthropogenic
Commercial Marine Vehicle	cmv_c1c2c3	Anthropogenic
Prescribed Fire	rxfire	Anthropogenic
Biogenic	biogenic	Natural
Wildfire	wildfire	Natural
Lightning NOx	ltnox	Natural
Non US Fire	nonus_fire	Natural
Sea Salt and Dimethyl Sulfide (DMS)	oceanic_seasalt	Natural
Windblown Dust	wbdust	Natural

The reported emissions that have the potential to impair visibility include sulfur dioxide (SO₂), nitrogen oxides (NO_x), particulate matter (PM₁₀ and PM_{2.5}), volatile organic compounds (VOCs), and ammonia (NH₃).

Section 4.1 includes a discussion on the inventories used in this analysis.

Sections 4.2 through 4.8 address important categories and potential contributors to visibility impairment in North Dakota.

4.1 Emission Inventories and Projections

The emission inventories addressed in this section include: 2002, 2011, 2014 (2014v2), Representative Baseline (RepBase), 2017, 2028 projections with planned reductions “on the books” (2028OTB), and 2028 projections with planned reductions on the books along with further potential additional controls (2028PAC). Each emissions inventory is detailed in the following sections.

The data presented in Sections 4.1.1 through 4.1.7 contain the summary of emissions for each inventory year and from each category analyzed. Summary emissions from 2014v2, RepBase, 2028 OTB, and 2028 PAC are included to show the emissions data from each category which was used in the WRAP modeling. Summary emissions from the 2017 NEI were included for comparison purposes to the 2014v2 and RepBase scenarios. Summary emissions from 2002 and 2011 were also included for comparison to the recent years.

4.1.1 2002 Inventory

The 2002 emissions used in this SIP revision are consistent with the 2002 emissions used in the March 3, 2010 SIP submittal by North Dakota. These data are provided for informational purposes and to show North Dakota’s emissions progress since 2002 per §51.308(f)(6)(v) and §51.308(g)(4).

The complete emissions data for the inventory year 2002 is displayed in Table 12. The sector data from 2002 was not compiled using the same sectors as the data from the current inventories used in the modeling (2014v2, RepBase, 2028OTB, and 2028PAC). The Department adjusted the 2002 data to best match the current sector data. Notable differences between the 2002 inventory and the current inventories include:

- North Dakota’s point source emissions in 2002 were for all point sources. To better align the data with the current breakdown for point sources (i.e. EGU, Non-EGU, and Oil and Gas), the Department allocated the 2002 emissions between “Electricity Generating Point” and “Industrial Point”, mainly to separate out EGUs. Specifically, “Electricity Generating Point” emissions of NO_x and SO₂ were itemized as these are the pollutants of most interest for regional haze and were the focus of additional reasonable progress controls.
- 2002 Fire data in Table 12 is for all fires, since the 2002 data was not broken down by types of fire (i.e. wildfire, prescribed fire, and agricultural fire).
- Ammonia emissions from the 2002 inventory were moved from the area source category (Remaining Nonpoint) to the “Agricultural Operations” category for the current inventories. The agriculture operations category was not a category used in 2002.

Table 12: 2002 Emissions Inventory for North Dakota (tons/year)

Sector	SO ₂	NO _x	VOC	NH ₃	PM ₁₀	PM _{2.5}
Fugitive Dust (area-source)	0	0	0	0	359,522	57,079
Agricultural Operations	29	43	0	118,398	0	0

^A VOC, NH₃, PM₁₀, and PM_{2.5} emissions are included with the “Industrial Point” Sector

4.1.2 2011 Inventory

The 2011 emissions used in this SIP revision are from the 2011 NEI and are consistent with the 2011 emissions used in the January 2015 progress report submitted by North Dakota. These data are provided to show North Dakota’s emissions progress over time per §51.308(f)(6)(v) and §51.308(g)(4). Consistent with the 2002 source categories as discussed in Section 4.1.1, the 2011 source categories were adjusted to be consistent with the current categories used in the modeling. The complete emissions data for inventory year 2011 is displayed in Table 13.

Table 13: 2011 Emissions Inventory for North Dakota (tons/year)

Sector	SO ₂	NO _x	VOC	NH ₃	PM ₁₀	PM _{2.5}
Fugitive Dust (area-source)	0	0	0	0	262,739	55,228

^A VOC, NH₃, PM₁₀, and PM_{2.5} emissions are included with the “Industrial Point” Sector

4.1.3 2014 Inventory (2014v2)

The 2014 NEI was used as the basis for the 2014v2 emissions scenario. 2014v2 is also the baseline emissions scenario used in modeling for round 2 planning purposes. The 2014 NEI was chosen as the starting point since this was the most complete emissions inventory available at the time planning began (i.e. 2017 NEI was not available). The “v2” is representative of data corrections made by states.⁷¹ WRAP states reviewed the 2014 NEI and made corrections to ensure the most accurate data was used in the modeling (Section 6). The RepBase and 2028 OTB inventories were constructed from the 2014v2 data. The future modeling scenarios, which use 2014v2 emissions data, have three important aspects to help ensure the most accurate results: 1) state reviewed/corrected NEI data, 2) quality assured IMPROVE data, 3) and metrological data. 2014v2 data was used in the model to determine the model’s accuracy when compared to the IMPROVE data, known as checking the model performance. A webpage was developed by WRAP outlining the model platform description and the model performance.⁷² Model Performance is discussed in Section 7.1. The 2014 emissions data used in the modeling are included in Table 14.

Table 14: 2014 Emissions Inventory for North Dakota (tons/year)

Sector	SO ₂	NO _x	VOC	NH ₃	PM ₁₀	PM _{2.5}

4.1.4 Representative Baseline (RepBase)

The Representative Baseline (RepBase) emissions reflect known changes to emissions relative to the 2014v2 data. Changes include items such as a facility installing controls post-2014 or emissions changes needed to better reflect normal/routine operations. For example, if a source was not operating in 2014, the emissions might need an upwards adjustment to better reflect current actual operations. Therefore, this scenario accurately reflects the current emissions profile for each source potentially impacting CIA visibility and can generally be thought of as a 3-year⁷³ (2016–2018) average of a stationary source's emissions. Another difference between the RepBase and 2014v2 emission scenarios is the use of RepBase average fire data vs actual 2014 fire data.⁷⁴ The RepBase emissions also serve as the most recent 'year' for which data are available and reviewed for accuracy.

The 2014v2 natural emissions (i.e., Biogenic, Sea Salt, lightning NO_x, and windblown dust) were used for the RepBase emissions inventory. The Representative Baseline emissions data used in the modeling are included in Table 15.

Table 15: Representative Baseline Emissions Inventory for North Dakota (tons/year)

Sector	SO ₂	NO _x	VOC	NH ₃	PM ₁₀	PM _{2.5}
Fugitive Dust (area-source)	0	0	0	0	186,929	32,975
Agricultural Operations	0	0	1,249	36,130	0	0
Agricultural Fire	403	1,188	1,655	6,399	5,253	3,459
Biogenic	0	44,573	179,876	0	0	0

https://views.cira.colostate.edu/docs/iwdw/platformdocs/WRAP_2014/RepBase_2028_CAMx_v3.pdf

4.1.5 2017 Inventory

A summary of the 2017 emissions from the NEI are presented in Table 16. These emissions were not used in any of the modeling completed by WRAP for this SIP revision but are being presented for comparative purposes and to meet the requirement of 40 CFR 51.308(g)(4). Note that natural emissions from sea salt, lightning NO_x, windblown dust, non-U.S. fires are not included in the 2017 NEI. Emissions from these categories are mostly insignificant except for lightning NO_x. Anthropogenic emissions from commercial marine vehicle are also not included in the 2017 NEI.

Table 16: 2017 National Emissions Inventory for North Dakota (tons/year)

Sector	SO ₂	NO _x	VOC	NH ₃	PM ₁₀	PM _{2.5}
Fugitive Dust (area-source)	0	0	0	0	392,393	60,803
Agricultural Operations	0	0	628	51,036	0	0
Agricultural Fire	313	830	2,945	4,922	3,221	2,075
Biogenic	0	36,109	121,047	0	0	0
Remaining Nonpoint	56,289	26,386	28,863	280	22,441	5,126

Total	109,274	180,579	559,779	60,409	438,624	85,536

4.1.6 2028 Inventory Projection (2028OTB)

The 2028OTB emissions reflect planned changes to emissions from the RepBase scenario scheduled to occur before 2028. The “OTB” stands for “on the books”, meaning that any controls, reductions, or facility shutdowns scheduled to occur prior to 2028 have been accounted for in this scenario. RepBase to 2028OTB differences include planned changes to coal fired EGUs and anticipated changes to upstream oil and gas operations, discussed in Sections 4.2.1 and 4.3.1, respectively. This scenario is also used as the baseline starting point for review of additional controls that may be needed for North Dakota to meet its RPGs. The 2028OTB emissions projections used in the modeling are included in Table 17.

Table 17: 2028 Emissions Projections for North Dakota (tons/year)

Sector	SO ₂	NO _x	VOC	NH ₃	PM ₁₀	PM _{2.5}
Fugitive Dust (area-source)	0	0	0	0	186,929	32,975

Total	60,806	209,385	640,870	44,616	206,324	48,125

4.1.7 2028 Inventory with Potential Additional Controls (2028PAC)

The 2028PAC emissions reflect the “potential additional controls” North Dakota evaluated to determine the impact these controls have on modeled visibility. The controls selected and associated emissions reductions were derived from North Dakota’s review of the four factor reports submitted by each company (Section 5.2, Appendix A, and Appendix B). The controls reviewed and selected for modeling are specific to NO_x and SO₂. The additional controls were selected on a rate basis (e.g. lb/MMBtu) and the associated tonnage was calculated using representative capacity factors for the unit. The anticipated tonnage reductions with the potential additional controls are displayed in Table 18. Any corresponding emissions changes of other visibility impairing pollutants were assumed insignificant. North Dakota had WRAP evaluate PAC at two levels.

The first iteration of PAC (2028PAC1) modeling evaluated the reduction of approximately 18,100 tons of SO₂ and approximately 4,100 tons of NO_x. These reductions came from the evaluation of additional controls at Otter Tail Power Company – Coyote Station (Section 5.2.1) and Basin Electric Power Cooperative – Antelope Valley Station (Section 5.2.2). Additionally, Unit 1 NO_x controls came online at Great River Energy – Coal Creek Station in spring 2020 and are included in the PAC1 controls. These

controls came online post- 2028OTB WRAP modeling deadline for 2028 projected inventory submittal. The NO_x controls installed on Unit 1 in 2020 are consistent with the proposed NO_x BART detailed in Section 8. Great River Energy was also evaluating options to upgrade Coal Creek Station's WFGD scrubber operations to reduce SO₂ and requested this scenario be included in the modeling. Overall, the 18,000 tons of modeled SO₂ reductions comprises of approximately 11,600 tons from Coyote Station, 5,800 tons from Antelope Valley Station, and 700 tons from Coal Creek Station. Due to the anticipated change in ownership at Coal Creek Station, the 700 tons of SO₂ reductions from Coal Creek Station are no longer being considered with this SIP revision. The 4,100 tons of modeled NO_x reductions comprises of approximately 3,100 tons from Coyote Station and 1,000 tons from Coal Creek Station. The 2028PAC1 scenario is representative of the maximum potential controls originally considered for this planning period.

The second iteration of PAC (2028PAC2) modeling evaluated the reduction of approximately 6,000 tons of SO₂ and approximately 1,000 tons of NO_x. These reductions came from the evaluation of upgraded controls at Otter Tail Power Company – Coyote Station (Section 5.2.1) and the same controls for Coal Creek included in 2028PAC1. Overall, the 6,000 tons of modeled SO₂ reductions comprises of approximately 5,300 tons from Coyote Station and 700 tons from Coal Creek Station. The 1,000 tons of NO_x reductions comes from the controls already installed at Coal Creek Unit 1. The 700 tons of SO₂ reductions from Coal Creek Station are no longer being considered with this SIP revision.

Table 18: 2028OTB Emissions with PAC reductions

Scenario	SO ₂	NO _x	OTB – PAC	
			SO ₂	NO _x
2028OTB	35,900	32,186	--	--
2028PAC1	17,779	28,059	18,121	4,127
2028PAC2	29,819	31,152	6,081	1,034

Table 18 only includes the emissions from the coal fired EGUs expected to remain operational beyond 2028. This includes Coyote Station, Antelope Valley Station, Leland Olds Station, Coal Creek Station, and Milton R. Young Station.

Note that 2028PAC1 and 2028PAC2 emissions are only included in Section 4.2.1 since all potential additional controls evaluated by North Dakota were specific to point source coal fired EGUs. A breakdown of the North Dakota coal fired EGU emissions is included in Section 4.2.1.1.

4.2 North Dakota Point Sources

Point sources are any large, stationary (non-mobile), identifiable sources of emissions that release pollutants into the atmosphere. A point source is a facility that is a major source under 40 CFR part 70 for one or more of the pollutants for which reporting is required by 40 CFR §51.15(a)(1).

Point sources in North Dakota include, but are not limited to: coal fired EGUs, petroleum refining, gas processing and transmissions facilities, ethanol manufacturing, and agricultural processing facilities.

Section 4.2.1 details the coal fired EGU emissions and Section 4.2.2 details all other point source emissions.

The visibility impairing pollutants for each of the emission inventory years from all North Dakota's point sources are listed in Table 19 and graphed in Figure 25.

Table 19: North Dakota Point Source Emissions (tons/year)

Pollutant	2002	2011	2014v2	RepBase	2028OTB
SO ₂	157,069	102,660	58,930	47,993	44,632
NO _x	87,438	61,266	56,846	43,408	41,235
VOC	2,086	3,812	6,382	6,445	6,367
NH ₃	518	5,724	1,275	1,256	1,256
PM ₁₀ ^B	565	1,419	6,874	6,653	6,388
PM _{2.5} ^A	2,002	4,006	5,145	5,036	4,777

^A For 2002 and 2011, PM_{2.5} ≈ Fine PM (FPM)

^B For 2002 and 2011, PM₁₀ ≈ Coarse PM (CPM)

Figure 25: North Dakota Point Source Emissions

As displayed in Table 19 and in Figure 25, emissions of NO_x and SO₂ have historically been the most significant visibility impairing pollutants in North Dakota and, relatively speaking, continue to be highest

emitted pollutants. As outlined in Section 5.1.1, ammonium nitrates and ammonium sulfates are the largest contributors to visibility impairment on the MIDs and also contribute to impairment on the clearest days. The emissions data paired with the visibility impairment supports North Dakota's four-factor evaluation that focused on NO_x and SO₂ controls on coal fired EGUs and other point sources.

4.2.1 North Dakota Coal Fired EGUs

The visibility impairing pollutants for each of the emissions inventory years from North Dakota's coal fired EGUs are listed in Table 20. NO_x emissions from coal fired EGUs accounted for 78% of the point source emissions and SO₂ emissions accounted for 82% of the point source emissions during the RepBase years.

Table 20: North Dakota Coal Fired EGU Emissions (tons/year)

Pollutant	2002	2011	2014v2	RepBase	2028OTB	2028PAC1	2028PAC2
SO₂	141,158	92,614	50,900	39,323	35,962	17,779	29,875
NO_x	75,362	51,015	46,410	33,712	31,539	28,059	31,482
VOC	NA ^B	NA ^B	635	633	625	625	625
NH₃	NA ^B	NA ^B	190	172	172	172	172
PM₁₀	NA ^A	NA ^A	3,744	3,575	3,338	3,338	3,338
PM_{2.5}	NA ^A	NA ^A	2,647	2,553	2,317	2,317	2,317

^A PM species for 2002 and 2011 tracked as FPM and CPM, included in Table 19.

^B VOC and NH₃ were not separated out in 2002 or 2011, total included in Table 19.

NO_x and SO₂ are the most significant visibility impairing pollutants and Figure 26 displays the significant progress North Dakota has made to reduce impacts from these pollutants.

Figure 26: North Dakota coal fired EGU NO_x and SO₂ Emissions

Emissions of NO_x and SO₂ have historically been the most significant visibility impairing pollutants emitted from North Dakota coal fired EGUs. This continues to be true. As outlined in Section 5.1.1, ammonium nitrates and ammonium sulfates are the largest contributors to visibility impairment on the MIDs and also contribute to impairment on the clearest days. The emissions data paired with the visibility impairment supports North Dakota's four-factor evaluations of additional NO_x and SO₂ controls on the coal fired EGUs. The projected 2028 visibility impact from the EGU sector is summarized in Section 3.1. The results of the additional controls evaluated for implementation is included in Section 6.1.1. A breakdown of the NO_x and SO₂ emissions, limits, and controls for each of the units at the five coal fired EGUs planned to be operating in 2028 is located in Section 4.2.1.1. For additional comparative purposes, North Dakota also quantified coal fired EGU emissions from nearby Canadian Power Stations from previous years. This information is discussed in Section 4.7.1.

4.2.1.1 North Dakota Coal fired EGU Facility Emissions

Section 4.2.1.1.1 and 4.2.1.1.2 contain a breakdown of SO₂ and NO_x emissions, respectively, for the North Dakota coal fired EGUs.

4.2.1.1.1 SO₂ Emissions from North Dakota Coal Fired EGUs

For direct comparison of emissions and controls at each individual coal fired EGU, see Table 21 and Table 22. Table 21 displays the SO₂ emissions history and future projections from each major unit for the coal fired EGUs in North Dakota.

Table 21: Individual Unit Past, Current, Future Projected SO₂ Emissions Profiles

Facility	Unit	2002	2014	RepBase	2028 OTB	2028 PAC1	2028 PAC2
Coyote	1	14,069	12,777	12,994	12,994	1,373	7,625
Antelope Valley	1	6,580	5,509	6,279	6,279	3,405	6,279
Antelope Valley	2	7,283	6,975	6,319	6,319	3,405	6,319
Leland Olds	1	16,655	412	636	636	636	636
Leland Olds	2	30,744	1,025	1,258	1,258	1,258	1,258

RM Heskett Station	1	622	1,030	753	0	0	0
RM Heskett Station	2	2,189	2,338	1,214	0	0	0
Stanton Station	1	8,900	2,493	0	0	0	0
Stanton Station	10	1,122	98	0	0	0	0
Total		141,156	50,551	39,242	35,900	17,779	29,819

Coyote Station has seen little change in routine SO₂ emissions since 2002 and is expecting operations to remain consistent through 2028. The Department selected additional controls for modeling evaluation to determine the impacts these controls have on overall visibility. Two varying levels of additional controls were reviewed and are displayed in the '2028PAC1' and '2028PAC2' columns in Table 21. For discussion on the controls selected for review, see Section 5.2.1. For discussion on the visibility impacts these potential controls had, see Section 6.1.1.

Antelope Valley Station Units 1 and 2 have seen little change in routine SO₂ emissions since 2002 and is expecting operations to remain consistent through 2028. The Department selected additional controls for modeling evaluation to determine the impacts these controls have on overall visibility. Additional controls were only evaluated in the '2028 PAC1' modeling run. For discussion on the controls selected for review, see Section 5.2.2. For discussion on the visibility impacts these potential controls had, see Section 6.1.1.

Leland Olds Station Units 1 and 2 have achieved significant reductions in emissions since 2002, each reducing SO₂ emissions by 96% from 2002 to RepBase. Each of these units currently emits below an annual rate of 0.10 lb SO₂ per MMBtu. No additional controls were selected for review on either unit. For discussion on the four factors review, see Section 5.2.3.

Coal Creek Station Units 1 and 2 have achieved significant reductions in emissions since 2002. Unit 1 and Unit 2 reduced SO₂ emissions by 71% and 73%, respectively, from 2002 to RepBase. Each of these units currently emits below an annual rate of 0.15 lb SO₂ per MMBtu. Prior to Great River Energy's end of coal announcement, the Department was working with Great River Energy on establishing lower allowable operating limits (near a rate of 0.10 lb SO₂ per MMBtu). As a result of these discussions, the Department evaluated 700 tons of SO₂ reductions for 2028 based on operational improvements the facility was

expecting to undertake at the time. Due to the anticipated change in ownership, the improvements are no longer being considered with this SIP revision.

Milton R. Young Units 1 and 2 have achieved significant reductions in emissions since 2002. Unit 1 and Unit 2 reduced SO₂ emissions by 96% and 75%, respectively, from 2002 to RepBase. Unit 1 currently emits below an annual rate of 0.1 lb SO₂ per MMBtu while Unit 2's annual rate is below 0.15 lb SO₂ per MMBtu. No additional controls were selected for review on either unit. For discussion on the four factors review, see Section 5.2.5.

Table 22: Individual Unit Projected 2028 SO₂ Emissions, Representative Performance Rate, Current Emissions Limits and Control Device

Facility	Unit	2028 Projected Emissions (tons) ^A	Representative Annual Performance Rate (lb/MMBtu)	Emissions Limit ^B	Control Device
Coyote	1	12,994	0.85	1.2 lb/MMBtu (3-hr rolling average)	Dry Flue Gas Desulfurization w/ Fabric Filter
Antelope Valley	1	6,279	0.36	1.2 lb/MMBtu (3-hr rolling average)	Dry Flue Gas Desulfurization w/ Fabric Filter
Antelope Valley	2	6,319	0.36	1.2 lb/MMBtu (3-hr rolling average)	Dry Flue Gas Desulfurization w/ Fabric Filter
Leland Olds	1	636	0.09	0.15 lb/MMBtu (30-day rolling average) ^C	Wet Flue Gas Desulfurization
Leland Olds	2	1,258	0.08	0.15 lb/MMBtu (30-day rolling average) ^C	Wet Flue Gas Desulfurization
Coal Creek	1	3,458	0.14	0.15 lb/MMBtu (30-day rolling average) ^C	Wet Flue Gas Desulfurization w/ reheat system
Coal Creek	2	3,400	0.14	0.15 lb/MMBtu (30-day rolling average) ^C	Wet Flue Gas Desulfurization w/ reheat system
Milton R. Young	1	766	0.07	0.15 lb/MMBtu (30-day rolling average) ^C	Wet Flue Gas Desulfurization
Milton R. Young	2	2,165	0.13	0.15 lb/MMBtu (30-day rolling average) ^{C,D}	Wet Flue Gas Desulfurization

^A Based off representative performance rate and operating capacity

^B Most strict emissions limits displayed. Other limits may apply as identified in the facility Title V Permit to Operate.

^C Or 95% reduction from inlet sulfur concentration

^D Or 90% reduction from inlet sulfur concentration and 0.15 lb/MMBtu (30-day rolling average)

Table 22 shows a comparison of the SO₂ performance rates and emissions limits from each of the units expected to be operating beyond 2028. Six of the nine units are subject to a limit of 0.15 lb SO₂ per MMBtu on a 30-day rolling average basis, established by the BART requirements of round 1. The BART facilities were Leland Olds Station, Coal Creek Station, and Milton R. Young Station. The three remaining units are subject to a limit of 1.2 lb SO₂ per MMBtu on a 3-hr rolling average basis, established by NSPS Subpart D. Each of these units is expected to operate in 2028 consistent with the information displayed in Table 22.

4.2.1.1.2 NO_x Emissions from North Dakota Coal Fired EGUs

For direct comparison of emissions and controls at each individual coal fired EGU, see Table 23 and Table 24. Table 23 displays the NO_x emissions history and future projections from each major unit for the coal fired EGUs in North Dakota.

Table 23: Individual Unit Past, Current, Future Projected NO_x Emissions Profiles

Facility	Unit	2002	2014	RepBase	2028 OTB	2028 PAC1	2028 PAC2
Coyote	1	13,173	11,375	7,363	7,363	4,270	7,363
Antelope Valley	1	5,840	3,127	1,697	1,697	1,697	1,697
Antelope Valley	2	5,953	5,866	1,708	1,708	1,708	1,708
Leland Olds	1	2,581	1,396	1,059	1,059	1,059	1,059
Leland Olds	2	11,184	5,174	4,192	4,192	4,192	4,192
Coal Creek	1	4,863	4,697	3,987	3,987	2,980	2,980
Coal Creek	2	5,492	3,287	3,010	3,010	2,983	2,983
Milton R. Young	1	8,510	3,195	3,435	3,435	3,435	3,435
Milton R. Young	2	14,335	4,998	5,735	5,735	5,735	5,735
RM Heskett Station	1	180	351	209	0	0	0
RM Heskett Station	2	918	984	978	0	0	0
Stanton Station	1	2,209	1,068	0	0	0	0
Stanton Station	10	890	603	0	0	0	0
Total		76,127	46,120	33,373	32,186	28,059	31,152

Coyote Station has achieved significant reductions in emissions since 2002, reducing NO_x by 44% from 2002 to RepBase. The Department selected additional controls for the modeling evaluation to determine the impacts these controls have on overall visibility. Additional controls were only evaluated in the '2028 PAC1' modeling run. For discussion on the controls selected for review, see Section 5.2.1. For discussion on the visibility impacts these potential controls had, see Section 6.1.1.

Antelope Valley Station Units 1 and 2 have achieved significant reductions in emissions since 2002, each reducing NO_x emissions by 71% from 2002 to RepBase. Each of these units currently emits at an annual rate of approximately 0.11 lb NO_x per MMBtu. No additional controls were selected for review on either unit. For discussion on the four factors review, see Section 5.2.2.

Leland Olds Station Units 1 and 2 have achieved significant reductions in emissions since 2002. Unit 1 and Unit 2 have reduced NO_x emissions by 59% and 63%, respectively, from 2002 to RepBase. Unit 1 currently

emits at an annual rate of 0.16 lb NO_x per MMBtu while Unit 2's annual rate is 0.29 lb NO_x per MMBtu. Each unit has SNCR installed and the difference in rate is attributed to the boiler type (wall fired versus cyclone). No additional controls were selected for review on either unit. For discussion on the four factors review, see Section 5.2.3.

Coal Creek Station Units 1 and 2 have achieved significant reductions in emissions since 2002. Unit 1 and Unit 2 reduced NO_x emissions by 18% and 45%, respectively, from 2002 to RepBase. Unit 1 has since reduced emissions further from the RepBase inventory, through installation of additional NO_x controls. Unit 1 NO_x controls were installed in the spring of 2020. Unit 2 currently emits an annual rate of 0.13 lb NO_x per MMBtu. Unit 1 is expected achieve similar annual NO_x performance rates as Unit 2. At the time of the WRAP modeling for 2028 OTB emissions, this project was not finalized and the reduction in NO_x for the Unit 1 was not included in the 2028 OTB projections. These reductions were incorporated for the 2028 PAC1 and 2028 PAC2 runs. The controls on Unit 1 result in an approximate 1,000 ton per year reduction in emissions. Prior to Great River Energy's end of coal announcement, the Department was working with Great River Energy and EPA Region 8 toward submittal of a revised BART analysis to lower the allowable operating limits (proposed rate of 0.15 lb NO_x per MMBtu on a 30-day rolling average basis). The Department has determined the appropriate course of action is to move forward with proposing a NO_x BART for Coal Creek Station. This proposal is included in Section 8.

Milton R. Young Units 1 and 2 have achieved significant reductions in emissions since 2002, each reducing NO_x emissions by 60% from 2002 to RepBase. Each of these units currently emits at an annual rate of approximately 0.33 lb NO_x per MMBtu. No additional controls were selected for review on either unit. For discussion on the four factors review, see Section 5.2.5.

Table 24: Individual Unit Projected 2028 NO_x Emissions, Representative Performance Rate, Current Emissions Limits and Control Device

Facility	Unit	2028 Projected Emissions (tons) ^A	Representative Annual Performance Rate (lb/MMBtu)	Emissions Limit ^B	Control Device
Coyote	1	7,363	0.46	0.50 lb/MMBtu (30-day rolling average)	Separated Overfire Air w/ Low-NOx Burners
Antelope Valley	1	1,697	0.11	0.17 lb/MMBtu (30-day rolling average)	Separated Overfire Air w/ Low-NOx Burners
Antelope Valley	2	1,708	0.11	0.17 lb/MMBtu (30-day rolling average)	Separated Overfire Air w/ Low-NOx Burners
Leland Olds	1	1,059	0.16	0.19 lb/MMBtu (30-day rolling average)	Low-NOx Burners w/ Selective Non-Catalytic Reduction and Separated Overfire Air

Facility	Unit	2028 Projected Emissions (tons) ^A	Representative Annual Performance Rate (lb/MMBtu)	Emissions Limit ^B	Control Device
Leland Olds	2	4,192	0.29	0.35 lb/MMBtu (30-day rolling average)	Selective Non-Catalytic Reduction w/ Separated Overfire Air
Coal Creek	1	3,987	0.13 ^C	Proposed: 0.15 lb/MMBtu (30-day rolling average) ^D Current: 5,104 lb/hr (12-month rolling average)	Low-NOX Burners w/ closed coupled overfired air w/ expanded overfired air registers in conjunction with DryFining™
Coal Creek	2	3,010	0.13	Proposed: 0.15 lb/MMBtu (30-day rolling average) ^D Current: 5,104 lb/hr (12-month rolling average)	Low-NOX Burners w/ closed coupled overfired air w/ expanded overfired air registers in conjunction with DryFining™
Milton R. Young	1	3,435	0.33	0.36 lb/MMBtu (30-day rolling average)	Selective Non-Catalytic Reduction w/ Advanced Separated Overfire Air
Milton R. Young	2	5,735	0.33	0.35 lb/MMBtu (30-day rolling average)	Selective Non-Catalytic Reduction w/ Advanced Separated Overfire Air

^A Based off representative performance rate and operating capacity

^B Most strict emissions limits displayed. Other limits may apply as identified in the facility Title V Permit to Operate. All limits are current unless otherwise specified.

^C Unit 1 controls came online in May 2020, 0.13 lb/MMBtu is the annual expected performance rate.

^D NO_x BART proposed with this SIP revision.

Table 24 shows a comparison of the NO_x performance rates and emissions limits from each of the units expected to be operating beyond 2028. Six of the nine units were BART eligible and installed controls to meet the BART requirements. Leland Olds Station and Milton R. Young have installed controls and

currently meet the BART requirements. Coal Creek Station has installed controls and complies with the North Dakota proposed NO_x BART requirements, included with this SIP revision in Section 8. Antelope Valley Station and Coyote Station were subject to reasonable progress requirements of regional haze round 1 and have meet these limits. Each of these units is expected to operate in 2028 consistent with the information displayed in Table 24.

4.2.2 North Dakota Other Point Sources

The visibility impairing pollutants for each of the emissions inventory years from North Dakota's remaining point sources are listed in Table 25. Included in these emissions totals are the point source Oil and Gas emissions from North Dakota facilities. NO_x emissions from these sources accounted for 22% of the point source emissions and SO₂ emissions accounted for 18% of the point source emission during the RepBase years.

Table 25: North Dakota non-EGU Point Source Emissions (tons/year)

Pollutant	2002	2011	2014v2	RepBase	2028OTB
SO₂	15,911	10,046	8,030	8,670	8,670
NO_x	12,076	10,251	10,436	9,696	9,696
VOC	NA ^B	NA ^B	5,747	5,812	5,742
NH₃	NA ^B	NA ^B	1,085	1,084	1,084
PM₁₀	NA ^A	NA ^A	3,130	3,078	3,050
PM_{2.5}	NA ^A	NA ^A	2,498	2,483	2,460

^A PM species for 2002 and 2011 tracked as FPM and CPM, included in Table 19.

^B VOC and NH₃ were not separated out in 2002 or 2011, total included in Table 19.

Of the visibility impairing pollutants, NO_x and SO₂ are the most significant, emissions are displayed in Figure 27.

Figure 27: North Dakota non-EGU Point Source NO_x and SO₂ Emissions

As displayed in Table 25, emissions of NO_x and SO₂ have historically been the most significant visibility impairing pollutants emitted from the non-EGU point sources in North Dakota. As is outlined in Section 5.1.1, ammonium nitrates and ammonium sulfates are the largest contributors to visibility impairment on the MIDs and also contribute to impairment on the clearest days. The emissions data paired with the visibility impairment supports North Dakota's four-factor evaluations of NO_x and SO₂ controls on the sources addressed in Sections 5.2.7 through 5.2.10. North Dakota notes that emissions from the point sources evaluated in Sections 5.2.7 through 5.2.10 are considerably smaller than the emissions from the coal fired EGU sector and any reductions from these sectors would likely be less impactful on improving visibility.

4.3 North Dakota Area and Non-Point Sources

All stationary sources not identified as point sources are classified as area or non-point sources. This includes emissions from minor stationary sources of air pollution and many of the sources of the Williston Basin oil and gas field within the Bakken Formation.

The visibility impairing pollutants for each of the emissions inventory years from all North Dakota's non-point and area sources are listed in Table 26 and graphed in Figure 28.

Table 26: North Dakota Area and Non-Point Source Emissions (tons/year)

Pollutant	2002	2011	2014v2	RepBase	2028OTB
SO ₂	10,515	2,728	4,214	9,562	15,374
NO _x	15,464	43,426	44,431	63,384	58,463
VOC	68,195	274,083	681,441	417,790	433,255
NH ₃ ^A	NA	NA	133	133	133
PM ₁₀ ^C	199	146	2,007	1,994	1,440
PM _{2.5} ^B	1,617	1,821	1,907	1,894	1,340

^A NH₃ was not tracked for 2002 and 2011.

^B For 2002 and 2011, PM_{2.5} ≈ FPM

^C For 2002 and 2011, PM₁₀ ≈ CPM

Figure 28: North Dakota Area and Non-Point Source NO_x and SO₂ Emissions

As detailed in Section 4.3.1 and as shown in Figure 29, a significant majority of the North Dakota's area and non-point source emissions are the result of upstream oil and gas operations. North Dakota reviewed the impacts from the oil and gas development in the state. This review is discussed in Section 5.2.11. North Dakota did not evaluate the visibility impacts from the remaining area and non-point sources since these emissions are insignificant when compared to the upstream oil and gas emissions.

Figure 29: North Dakota Upstream Oil and Gas and Other Non-Point Emissions

4.3.1 North Dakota Oil and Gas Upstream

The visibility impairing pollutants for each of the emissions inventory years from all of North Dakota's upstream oil and gas sector are listed in Table 27 and graphed in Figure 30. NO_x and SO₂ emissions from upstream oil and gas operations each accounted for 98% of the emissions of the total RepBase inventory for area and non-point sources. VOC emissions from this industry account for 96% of the area and non-point total. VOC emissions are also included in Figure 30.

Table 27: North Dakota's Upstream Oil and Gas Emissions (tons/year)

Pollutant	2002	2011	2014v2	RepBase	2028OTB
SO ₂	4,958	2,073	4,043	9,391	15,203
NO _x	4,631	25,277	43,237	62,190	57,269
VOC	7,740	252,920	664,297	400,646	416,111
PM ₁₀	NA ^A	NA ^A	1,129	1,116	562
PM _{2.5}	NA ^A	NA ^A	1,129	1,116	562

^A PM species for 2002 and 2011 were not separated for the oil and gas source category.

Figure 30: North Dakota Upstream Oil and Gas SO₂, NO_x, and VOC Emissions

As is displayed in Table 27 and Figure 30, emissions of NO_x, SO₂, and VOC have historically been the most significant visibility impairing pollutants emitted from North Dakota’s upstream oil and gas operations. As is outlined in Section 5.1.1, ammonium nitrates and ammonium sulfates are the largest contributors to visibility impairment on the MIDs and also contribute to impairment on the clearest days. The emissions data paired with the visibility impairment data supports North Dakota’s review of the impacts from the oil and gas operations (Section 5.2.11). For comparative purposes, North Dakota also quantified upstream oil and gas emissions from Canadian oil and gas operations from previous years. This information is discussed in Section 4.7.2.

4.4 North Dakota Non-Road Mobile

The visibility impairing pollutants for each of the emissions inventory years from all North Dakota’s non-road mobile sources are included in Table 28 and graphed in Figure 31. This information was prepared by WRAP for use in regional haze planning and modeling. The project overview states: “For western U.S. regional analysis using photochemical modeling for Regional Haze, WESTAR-WRAP is assisting state and local air agencies to review and, to the extent necessary and feasible, revise the 2028 future year mobile sources (i.e., on-road, off-road equipment, rail, marine, and airport) emission inventories. The basis of the future year 2028 mobile source emission inventories will utilize both the WRAP 2014NEIv2 dataset as well as the 2014-2016 National Emissions Modeling Collaborative 2016v1 future year 2028 inventory, with revisions per state agency input. The process allows participants to review and provide updates to these emissions inventories. Feedback and revisions to the inventories will be incorporated into air quality

modeling by the WRAP for regional photochemical modeling.”⁷⁵ A memorandum which discusses detailed information regarding the baseline inventory and future year inventory was also developed to support the WRAP states.⁷⁶ North Dakota did not recommend any changes to these inventories.

Table 28: North Dakota Non-Road Mobile Emissions (tons/year)

Pollutant	2002	2011	2014v2	RepBase	2028OTB
SO ₂	7,246	68	44	40	32
NO _x	55,502	31,183	26,182	28,060	12,200
VOC	13,515	10,452	8,585	7,208	4,762
NH ₃	33	30	31	37	38
PM ₁₀	NA ^A	NA ^A	2,207	2,278	852
PM _{2.5}	NA ^A	NA ^A	2,132	2,201	819

^A PM species for 2002 and 2011 tracked as FPM and CPM.

Figure 31: North Dakota Non-Road Mobile NO_x and SO₂ Emissions

⁷⁵ Available at: <http://views.cira.colostate.edu/wiki/wiki/11203/mobile-source-emissions-inventory-projections-project> (Last visited December 28, 2020)

⁷⁶ Available at: https://views.cira.colostate.edu/docs/wrap/mseipp/WRAP_MSEI_Summary_Memo_13Mar2020.pdf (Last visited December 28, 2020)

As seen in Table 28, implementation of federal low sulfur fuel standards has nearly eliminated SO₂ emissions from this sector. The SO₂ emissions from 2011, 2014v2, RepBase, and 2028OTB were too small to show up in Figure 31. Note the 2028OTB NO_x emission value in Table 28. Significant reductions are projected for future NO_x emissions as less efficient engines are replaced with higher efficient combustion engines and/or are replaced with electric engines, as is detailed in Section 5.3.1.2.5.

4.5 North Dakota On-Road Mobile

The visibility impairing pollutants for each of the EI years from all North Dakota's on-road mobile sources are included in Table 29 and Figure 32. This information was prepared by WRAP for use in regional haze planning and modeling.⁷⁷ A memorandum which discusses detailed information regarding the baseline inventory and future year inventory was also developed to support the WRAP states.⁷⁸ North Dakota did not recommend any changes to these inventories.

Table 29: North Dakota On-Road Mobile Emissions (tons/year)

Pollutant	2002	2011	2014v2	RepBase	2028OTB
SO ₂	812	95	91	91	53
NO _x	24,746	21,193	33,305	33,305	8,051
VOC	12,814	8,377	10,753	10,753	3,831
NH ₃	732	346	343	343	259
PM ₁₀	NA ^A	NA ^A	1,884	1,884	808
PM _{2.5}	NA ^A	NA ^A	1,320	1,320	308

^A PM species for 2002 and 2011 tracked as FPM and CPM

⁷⁷ Available at: <http://views.cira.colostate.edu/wiki/wiki/11203/mobile-source-emissions-inventory-projections-project> (Last visited December 28, 2020)

⁷⁸ Available at: https://views.cira.colostate.edu/docs/wrap/mseipp/WRAP_MSEI_Summary_Memo_13Mar2020.pdf (Last visited December 28, 2020)

Figure 32: North Dakota On-Road Mobile NO_x and SO₂ Emissions

As seen in Table 29, implementation of federal low sulfur fuel standards has nearly eliminated SO₂ emissions from this sector. The SO₂ emissions from 2011, 2014v2, RepBase, and 2028OTB were too small to show up in Figure 32. Note the 2028OTB NO_x emission value in Table 29. Significant reductions are projected for future NO_x emissions as less efficient engines are replaced with higher efficient combustion engines and/or are replaced with electric engines (Section 5.3.1.2).

4.6 North Dakota Natural Emissions

Natural sources of visibility impairing emissions include biogenic, lightning NO_x, windblown dust, sea salt, non-US fires and US wildfires. North Dakota emissions from each emissions inventory year and for each of these source categories are included in Section 4.1 (Table 12 through Table 17).

For North Dakota CIAs, it should be noted that impacts from wildfires outside of North Dakota are generally eliminated from consideration when using the MIDs metric versus the haziest days. Due to the haziest days being typically associated with wildfire events and the MIDs attempts to focus on anthropogenic emissions. Emissions from wildfires for all the WRAP states can be found in Section 4.8.

4.7 International Emissions from Canada

North Dakota shares an international border with the Canadian Provinces of Manitoba and Saskatchewan. The anthropogenic NO_x, SO₂, and VOC emissions from these provinces have been summarized in Table 30 and are displayed in Figure 33. These emissions have been included with this analysis to show the magnitude of these provinces' emissions compared to North Dakota. The inventory years displayed in

Table 30 were selected because they align well with the inventory years used for North Dakota emissions and WRAP modeling. 2002 emissions from US and Canada are directly comparable. 2014 emissions from Canada are comparable to the 2014v2 scenario used by North Dakota. 2017 emissions from Canada are comparable to the RepBase scenario used by North Dakota. The magnitude of the 2017 international emissions helps support the use of an adjusted glidepath for North Dakota CIAs (Section 3.2.7). Also included in Table 30 are total emissions from the Canadian provinces of Alberta and British Columbia, both provinces are upwind of the prevailing wind direction in North Dakota and have the potential to cause visibility impairment in North Dakota CIAs. North Dakota obtained the Canadian emissions data online from the government of Canada website.⁷⁹

Table 30: Total Canadian and North Dakota Anthropogenic Emissions (tons/year)

Source	Pollutant	Year		
		2002	2014	2017
Alberta	NOx	852,170	750,454	703,884
	SO ₂	516,596	318,555	264,988
	VOC	655,958	722,539	595,413
British Columbia	NOx	387,105	298,608	303,225
	SO ₂	104,568	113,350	80,728
	VOC	314,759	180,296	168,170
Manitoba	NOx	69,449	50,501	48,013
	SO ₂	419,587	174,678	131,559
	VOC	78,212	63,919	60,477
Saskatchewan	NOx	185,937	164,949	159,831
	SO ₂	150,848	116,920	125,633
	VOC	222,835	260,964	272,978
Total of four the Canadian Provinces	NOx	1,494,661	1,264,512	1,214,953
	SO ₂	1,191,599	723,503	602,907
	VOC	1,271,763	1,227,719	1,097,038
North Dakota	NOx	183,150	160,764	168,157
	SO ₂	175,642	63,279	57,686
	VOC	96,610	707,161	442,196

Figure 33: Anthropogenic Emissions from the Four Combined Canadian Provinces and North Dakota

4.7.1 Nearby Canadian Coal fired EGUs

Table 31 and Figure 34 compare North Dakota coal fired EGU emissions to nearby Canadian coal fired EGUs. The three nearby Canadian facilities were included in this analysis since North Dakota's CIAs are likely impacted by emissions from these sources because they have significant NO_x and SO₂ emissions, are near North Dakota CIAs, and are upwind from the local prevailing wind direction. The locations of Boundary Dam Power Station (813 Mwe), Shand Power Station (279 Mwe), and Poplar River Power Station (630 Mwe) are displayed in Figure 35 along with the North Dakota four factor sources.

Table 31: Nearby Canadian and North Dakota Coal fired EGU Emissions (tons/year)

Source	Pollutant	2002	2017	Difference (2017 – 2002)
Boundary Dam Power Station	SO ₂	47,338	30,037	-17,302
	NO _x	18,950	14,009	-4,941
Poplar River Power Station	SO ₂	47,098	44,589	-2,509
	NO _x	12,862	13,574	+712
Shand Power Station	SO ₂	13,383	10,507	-2,876
	NO _x	6,080	3,419	-2,661
	SO₂	107,819	85,133	-22,686

Source	Pollutant	2002	2017	Difference (2017 – 2002)
Total of three nearby Canadian Coal fired EGUs	NO _x	37,892	31,002	-6,889
Total From North Dakota Coal fired EGUs	SO ₂	141,158	39,323	-101,835
	NO _x	75,362	33,712	-41,650

As of 2017, the three Canadian facilities had the potential to generate 1,722 Mwe of electricity. 2017 emissions of NO_x and SO₂ totaled just over 116,000 tons. North Dakota coal fired EGUs had the potential to generate over 4,000 Mwe. 2017 emissions of NO_x and SO₂ totaled approximately 73,000 tons. Overall, from the years of 2002 through 2017, North Dakota's coal fired EGUs have achieved a combined NO_x and SO₂ emissions reduction of 66% while these Canadian EGU's decreased only 20%. Figure 34 shows the magnitude of the reductions achieved in North Dakota since 2002 as compared to the Canadian EGUs.

Figure 34: Nearby Canadian and North Dakota Coal fired EGU Emissions (tons/year)

Figure 35: North Dakota Four Factor Sources and Nearby Canadian Coal fired Power Plants

4.7.2 Canadian Upstream Oil and Gas

Table 32 and Figure 36 illustrate a comparison between North Dakota upstream oil and gas emissions and Canadian upstream oil and gas emissions. North Dakota's CIAs are likely impacted by emissions from these Canadian sources since they have significant VOC, NO_x and SO₂ emissions and are upwind from the prevailing wind direction. The data were gathered from the Environment and Climate Change Canada website.⁸⁰ Emissions attributable to natural gas production and processing, natural gas transmission and storage, petroleum liquids storage and petroleum liquids transportation were not included in Table 32 because these subsectors are not included North Dakota's upstream oil and gas inventory. North Dakota's emissions from these activities are quantified in the point source emissions and non-point source emissions.

⁸⁰ Available at: <https://pollution-waste.canada.ca/air-emission-inventory/> (Last Visited May 17, 2021).

Table 32: Canadian and North Dakota Upstream Oil and Gas Emissions (tons/year)

Source	Pollutant	2002	2017	Difference (2017-2002)
Alberta	NOx	78,338	119,402	+41,064
	SO ₂	147,531	90,700	-56,831
	VOC	303,801	300,851	-2,949
British Columbia	NOx	4,777	3,548	-1,229
	SO ₂	3,044	1,188	-1,856
	VOC	10,918	5,196	-5,722
Manitoba	NOx	46	234	+187
	SO ₂	409	1,154	+746
	VOC	3,682	7,614	+3,932
Saskatchewan	NOx	8,125	10,876	+2,750
	SO ₂	7,649	12,483	+4,833
	VOC	104,491	171,528	+67,037
Total of the four Canadian Provinces	NOx	91,287	134,059	+42,772
	SO ₂	158,633	105,525	-53,108
	VOC	422,892	485,190	+62,298
North Dakota	NOx	4,631	62,190	+57,559
	SO ₂	4,958	9,391	+4,433
	VOC	7,740	400,646	+392,906

As shown in Table 32, most of the Canadian upstream oil and gas emissions come from Alberta and Saskatchewan. Alberta and Saskatchewan account for over 97% of all SO₂, NO_x, and VOC emissions from the Canadian upstream oil and gas sector. These emissions primarily result from the Canadian oil sands, the third-largest proven oil reserve in the world.⁸¹ The oil sands are primarily located in Alberta, northeast of Edmonton.⁸²

Figure 36: Canadian and North Dakota Upstream Oil and Gas Emissions (tons/year)

4.8 Wildfire Emissions from WRAP States

The WRAP Fire and Smoke Workgroup developed emissions profiles for the 2014v2 and the RepBase inventories. The 2014 base year inventory used EPA’s 2014 Wildland Fire EI, version 2 as the starting point.⁸³ WRAP state and stakeholder input was received starting from this inventory. North Dakota had no comments regarding the data for North Dakota or other states. The RepBase inventory was developed starting from the 2014v2 data and serves as a typical or average fire year observed during the period of 2014–2018. Wildfire activity across the United States can vary greatly from year to year across three primary degrees of freedom: space, time, and magnitude. Therefore, building a single-year inventory dataset that captures “average” wildfire activity over the multi-year baseline period is difficult, but was completed for this exercise. Full details of how this was done can be found in the detailed report outlining this project.⁸⁴

The visibility impairing pollutant emissions for the 2014v2 and RepBase scenarios are shown in Table 33 and Table 34, Respectively. Particulate matter (PM₁₀ and PM_{2.5}) are the largest visibility impairing pollutants from this activity. To help show the magnitude in differences of these emissions from each state, a pie chart comparing the PM_{2.5} emissions from all the WRAP states is shown in Figure 37. Figure 37 includes PM_{2.5} from both the 2014v2 and RepBase inventories. When comparing 2014v2 to RepBase fire emission inventories, it is easily noticed that 2014 was a low fire activity year and the RepBase inventory

⁸³ Available at: ftp://newftp.epa.gov/air/nei/2014/doc/2014v2_supportingdata/wild_and_prescribed_fires/ (Last visited August 23, 2018)

⁸⁴ Available at: https://www.wrapair2.org/pdf/fswg_rhp_fire-ei_final_report_20200519_FINAL.PDF (Last visited December 30, 2020)

is likely more representative of actual wildfire activity. The low 2014 fire activity was supported by the IMPROVE data, as discussed in Section 3.3.

Table 33: 2014v2 Wildfire Emissions from WRAP States (tons)

State	VOC	NO _x	SO ₂	PM ₁₀	PM _{2.5}

5 §51.308(f)(2) – Long Term Strategy for North Dakota

5.1 §51.308(f)(2)(i) – Source Screening

The Department focused its control strategy analysis on emissions of NO_x and SO₂ for the second planning period. NO_x and SO₂ are the two main species which react to form ammonium nitrates and ammonium sulfates, the main visibility impairing species that affect visibility at CIAs in North Dakota on the MIDs (Section 5.1.1). On an individual unit basis, point sources are the largest contributors to SO₂ and NO_x. Therefore, the Department elected to focus on existing point sources in this planning period (Section 5.2.1 through Section 5.2.10). The Department also evaluated oil and gas upstream operations in North Dakota (Section 5.2.11). Weighted emissions potential (WEP) and area of influence (AOI) modeling using projected 2028 emissions was completed by WRAP.⁸⁵ These products supported the Department's focus on existing point sources and oil and gas upstream operations during this planning period. Refer to Appendix C for the WEP/AOI analysis for North Dakota and nearby CIAs.

5.1.1 Ammonium Sulfates and Ammonium Nitrates

5.1.1.1 Most Impaired Days

On the MID, LWA and TRNP were both primarily impacted by ammonium nitrates and ammonium sulfates from 2000–2018. Figure 38 displays the annual average light extinction information for LWA and Figure 39 displays this information for TRNP. These data indicate the Department should focus four-factor analysis reviews on controls to reduce sulfur dioxide (SO₂) and nitrogen oxides (NO_x) from anthropogenic sources in North Dakota.

⁸⁵ Available at: <https://views.cira.colostate.edu/tssv2/WEP-AOI/> (Last visited February 22, 2021)

Figure 38: Annual Average Light Extinction at LWA for the Most Impaired Days from 2000–2018.⁸⁶

Figure 39: Annual Average Light Extinction at TRNP for the Most Impaired Days from 2000–2018.⁸⁷

⁸⁶ Available at: <https://views.cira.colostate.edu/tssv2/Express/VisTools.aspx>

⁸⁷ Available at: <https://views.cira.colostate.edu/tssv2/Express/VisTools.aspx>

5.1.1.2 Clearest Days

LWA and TRNP were most significantly impacted by ammonium sulfates from 2000–2018 on the clearest days. Organic mass, coarse mass, elemental carbon, and ammonium nitrates also contribute to visibility impairment on the clearest days at LWA and TRNP. Figure 40 displays this information for LWA and Figure 41 displays this information for TRNP.

Figure 40: Annual Average Light Extinction at LWA for the Clearest Days from 2000–2018.⁸⁸

⁸⁸ Available at: <https://views.cira.colostate.edu/tssv2/Express/VisTools.aspx>

Figure 41: Annual Average Light Extinction at TRNP for the Clearest Days from 2000–2018.⁸⁹

There are no significant recent anomalies with the annual average light extinction on the clearest days.

5.1.2 Determination of Subject Facilities

Initial planning stages for the second planning period for regional haze required that North Dakota determine how to choose facilities that would be required to submit a report detailing available emissions reduction measures in consideration of the four statutory factors. The facilities required to submit these reports were selected based on recent average annual emissions of SO₂ and NO_x and their distance to the nearest CIA. This is also known as Q/d, where “Q” represents emissions, in tons, and “d” represents distance, in kilometers. Sulfur dioxide (SO₂) and nitrogen oxides (NO_x) were the primary focus since these are the pollutants which contribute the most to anthropogenic visibility impairment in North Dakota CIAs (Section 5.1.1). Table 35 lists the primary facilities that North Dakota evaluated. The facilities in Table 35 were chosen based on their proximity to CIAs and total emissions of SO₂ and NO_x. All electrical generating utilities (EGUs) were included in the Department’s initial screening to determine if the company should submit a report detailing available emissions reduction measures. The emissions used to determine Q/d were average annual emissions for 2012 through 2016. The Department then considered other point sources near CIAs. After reviewing the facilities listed in Table 35, the Department determined that the cutoff for facilities that the Department would require to submit a report detailing available emissions reduction measures would be if any emission unit at the facility has a Q/d of 10. As such, Great River Energy was not required to submit a report for the Spiritwood Station. Although the Great River Energy Stanton Station was operational between 2012 and 2016, as is shown in Table 35, the facility was shut

⁸⁹ Available at: <https://views.cira.colostate.edu/tssv2/Express/VisTools.aspx>

down on May 1, 2017. Therefore, a letter requesting a report was not sent to Great River Energy for the Stanton Station. Although the Northern Border Pipeline Company has a Q/d of 9, they were still required to submit a report to the Department since the facility was close to the Q/d threshold.

Table 35: Facility emissions relative to distance from Class I areas.

Permittee	Facility	SO₂ + NO_x Emissions (tons) ^A	Nearest Class I area	Distance to Nearest Class I area (km)	Q/d to Nearest Class I area
Basin Electric Power Cooperative	Antelope Valley Station (Unit 1)	10,592	TRNP (NU) ^B	117	91

^E No letter requesting a report on emissions reductions measures was sent due to the low Q/d

^F Lostwood National Wildlife Refuge Wilderness Area

5.2 §51.308(f)(2)(i) – Four Factors Analyses for Point Sources

As is illustrated in Table 35, the point sources shown in Figure 42 submitted a report on emissions reductions measures in consideration of the four statutory factors to the Department as part of North Dakota's long-term strategy planning, as required by 40 CFR §51.308(f)(2)(i). Ten facilities were required to submit this report. These ten facilities are addressed in Sections 5.2.1 through 5.2.10. In addition to these ten facilities, North Dakota upstream oil and gas development was reviewed and is discussed in Section 5.2.11. Oil and gas upstream sources are considered nonpoint sources and are part of a "group of sources". Oil and gas point sources (e.g. Hess Tioga Gas Plant) are, however, included in the oil and gas sector category for modeling. The combined NO_x and SO₂ emissions from this category are similar to the aggregate emissions from the coal fired EGU sector (See Sections 4.2.1 and 4.3.1).

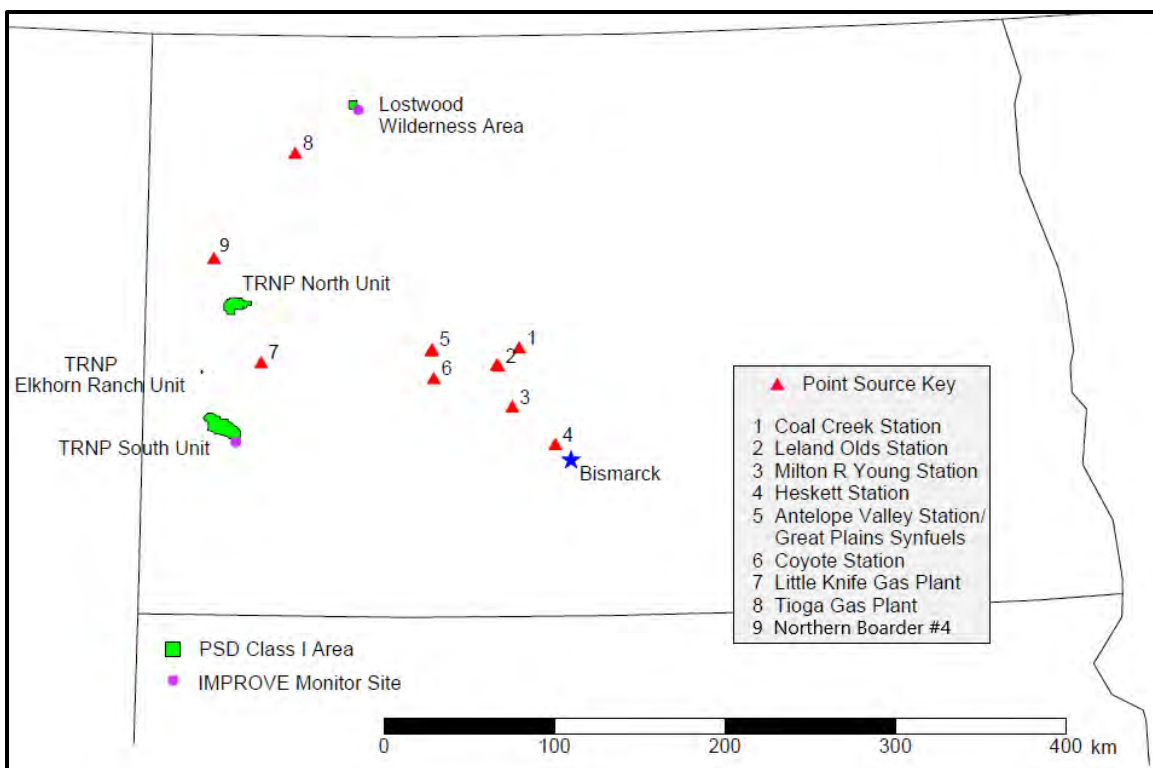

Figure 42: Locations of the point sources that submitted a four factors analysis as part of North Dakota's long-term strategy planning.

5.2.1 Otter Tail Power Company – Coyote Station

Otter Tail Power Company – Coyote Station (Coyote) is a single unit EGU with a capacity to produce approximately 450 megawatts (MW) per hour of electricity. The boiler is a Babcock and Wilcox cyclone fired boiler with a heat input capacity of 5,800 million British thermal units (MMBtu) per hour. Coyote commenced operation in 1981. Coyote is located in Mercer County about three miles southwest of the town of Beulah, North Dakota. Coyote is a mine-mouth power plant which receives coal from North American Coal Company – Coyote Creek Mine.

As documented in Table 35, Coyote Station has a Q/d of 164, which is above the threshold of 10. Therefore, the Department sent a letter to Otter Tail Power Company on May 2, 2018, requesting an evaluation of additional potential control measures.⁹⁰ The letter required that the report be submitted to the Department on or before January 31, 2019. Otter Tail Power Company submitted their original report to the Department on January 30, 2019. The Department submitted comments regarding areas of concern in the report to Otter Tail Power Company on March 20, 2019.⁹¹ A revised report was provided by Otter Tail Power Company on May 10, 2019. An additional report from Otter Tail Power Company was submitted to the Department on January 6, 2020, containing an update to the costs for the installation and operation of selected non-catalytic reduction (SNCR) and rich reagent injection (RRI). A final Otter Tail Power Company report was submitted to the Department on June 8, 2020, containing an update to the analysis associated with some of the SO₂ controls evaluated. A copy of each submittal by Otter Tail Power Company can be found in Appendix B.1.b.

The Department evaluated the information submitted by Otter Tail Power Company and conducted its own independent four factor analysis to determine the appropriate control requirements for Coyote Station. Based on the Department's evaluation of all sources of information, future operations and emissions profiles are expected to remain consistent with current conditions. Additionally, the control cost estimations presented in the Department's four-factor analysis are accurate and consistent with Department experience based on past analysis of source control costs. The Department's four-factor analysis of Coyote Station's additional control measures evaluation can be found in Appendix A.1.

The Department's consideration and application of the four factors (as set forth in Appendix A.1) are summarized as follows. Time necessary for compliance was determined not to be significant enough to discount any control measures. Energy and non-air quality environmental impacts were determined not to be significant enough to eliminate any of the control measures. Remaining useful life was determined by the Department to not eliminate any control measures. Therefore, cost of compliance was most heavily considered by the Department in selection of additional controls for modeling review and to determine if these controls are appropriate and necessary to demonstrate reasonable progress.

Additional SO₂ and NO_x controls were selected to be included in the 2028 potential additional controls (PAC) visibility modeling based on the Department's consideration of the four factors. The Department evaluated additional controls for Coyote using two scenarios.

The first additional controls modeling scenario contained the selection of controls in line with the control technologies and emissions rates of similar EGUs which were subject to the BART requirements. The SO₂ controls selected for the first modeling evaluation included a reduction of approximately 11,600 tons from the baseline 2028 emissions. This reduction could be accomplished by replacing the existing SO₂ absorber module. The replacement SO₂ absorber module's capital cost is approximately \$110 million, annualized cost is approximately \$21 million, and the cost per ton of SO₂ reduced is approximately \$1,800. The NO_x controls selected for this evaluation included a reduction of approximately 3,000 tons from the baseline

⁹⁰ Appendix B.1.a.

⁹¹ Appendix B.1.c.

2028 emissions. This reduction could be accomplished by the installation of a selective non-catalytic reduction (SNCR) controls. The SNCR's capital cost is approximately \$20 million, annualized cost is approximately \$5 million, and the cost per ton of NO_x reduced is approximately \$1,700. Also included in the first scenario modeling were reductions from Antelope Valley Station, see Section 5.2.2.

The second additional controls modeling scenario contained the selection of controls based on limited capital expenditure and facility modifications, while still achieving sizable reductions. This resulted in selecting modifications of the flue gas desulfurization (FGD) controls to improve the efficiency of the unit. The second modeling evaluation included a reduction of approximately 5,300 tons of SO₂ from the baseline 2028 emissions. The FGD improvements capital cost is approximately \$500,000, annualized cost approximately \$2.1 million, and cost per ton of SO₂ reduced is approximately \$400. There were no additional NO_x controls selected with this modeling scenario. There were also no additional reductions from other sources included in this scenario. Therefore, in this modeling scenario, the second additional controls modeling shows the impact reducing 5,300 tons of SO₂ from Coyote has on the overall 2028 projected visibility conditions.

The results of the visibility modeling evaluation for the 2028 first and second potential additional controls scenarios are addressed in Section 6.1.1. The first scenario resulted in a projected improvement of 0.08 deciviews at TRNP and 0.1 deciviews at LWA on the IMRPOVE MIDs. Again, the first scenario also includes reductions from Antelope Valley Station (Section 5.2.2). The second scenario resulted in a projected improvement of 0.03 deciviews at TRNP and 0.04 deciviews at LWA on the IMPROVE MIDs. The second scenario reflects the projected visibility improvement from SO₂ reductions only at Coyote Station. These visibility improvements modeled for the first and second potential additional controls scenarios are not considered significant since the improvements are smaller than what is perceptible by an unaided human eye.

Since the modeling has indicated no expected significant change in visibility (Section 6.1.1) and TRNP and LWA are projected to achieve the adjusted uniform rate of progress required by 2028 (Section 3.1 and 6.1.1), the Department does not believe any additional SO₂ or NO_x controls at Coyote should be required for installation during this planning period. The Department will re-evaluate this decision during the 2025 progress report.

5.2.2 Basin Electric Power Cooperative – Antelope Valley Station

Basin Electric Power Cooperative – Antelope Valley Station (AVS) is a two-unit electrical generating utility (EGU). Each unit has the capacity to produce approximately 470 megawatts (MW) per hour of electricity. Unit 1 and Unit 2 are identical Combustion Engineering boilers firing pulverized lignite coal tangentially. Unit 1 and Unit 2 each have a heat input capacity of 6,275 MMBtu per hour. Unit 1 began commercial operation in 1984. Unit 2 began commercial operation in 1986. AVS is located in Mercer County about eight miles northwest of the town of Beulah, North Dakota and approximately six miles north of US Highway 200. AVS receives most of its lignite coal from the coal that is too fine-grained to be used by the Great Plains Synfuels Plant (GPSP). GPSP is located just south of AVS. The remaining coal is delivered from the nearby Freedom Mine, which is located approximately two miles north of AVS.

As documented in Table 35, AVS Unit 1 has a Q/d of 91 and AVS Unit 2 has a Q/d of 104. Therefore, the Department sent a letter to Basin Electric Power Cooperative (Basin) on May 2, 2018, requesting an evaluation of additional potential control measures.⁹² The letter required that the report be submitted to the Department on or before January 31, 2019. Basin's original report was submitted to the Department on January 31, 2019.⁹³ The Department provided comments to address areas of concern in Basin's report on June 20, 2019.⁹⁴ Basin submitted a response to the Department's comments on July 12, 2019.⁹⁵ A copy of each submittal by Basin AVS can be found in Appendix B.2.b.

The Department evaluated the information submitted by Basin and conducted its own independent four factor analysis to determine the appropriate control requirements for AVS. Based on the Department's evaluation of all sources of information, future operations and emissions profiles are expected to remain consistent with current conditions. Additionally, the control cost estimations presented in the Department's four-factor analysis are accurate and consistent with Department experience based on past analysis of source control costs. The Department's four-factor analysis of Basin AVS's additional control measures evaluation can be found in Appendix A.2.

The Department's consideration and application of the four factors (as set forth in Appendix A.2) are summarized as follows. Time necessary for compliance was determined not to be significant enough to discount any control options. Energy and non-air quality environmental impacts were determined not to be significant enough to eliminate any of the control options. Remaining useful life was determined by the Department to not eliminate any control options. Therefore, cost of compliance was most heavily considered by the Department in selection of additional controls for modeling review and to determine if these controls are appropriate and necessary to demonstrate reasonable progress.

Additional SO₂ controls were selected to be included in the 2028 potential additional controls visibility modeling based on the Department's consideration of the four factors. No NO_x controls were selected for the modeling evaluation since the facility operates at a low baseline NO_x rate and none of the controls were deemed economically reasonable for evaluation.

The first additional controls modeling scenario contained the selection of controls in line with the control technologies and emissions rates of similar EGUs which were subject to the BART requirements. The SO₂ controls selected in the first modeling evaluation included a reduction of approximately 5,800 tons from the baseline 2028 emissions. Unit 1 and Unit 2 would each experience roughly 2,900 tons of reductions. The 2,900 tons of reductions for each unit could be accomplished by increasing the stoichiometric ratio (Ca:S) on the existing flue gas desulfurization unit. These upgrades come at a capital cost of approximately \$10 million, annualized cost of approximately \$2 million, and the cost per ton of SO₂ reduced is approximately \$700. Also included in the first scenario modeling were reductions from Coyote Station, see Section 5.2.1.

⁹² Appendix B.2.a.

⁹³ Appendix B.2.b.

⁹⁴ Appendix B.2.c.

⁹⁵ Appendix B.2.c.

No controls were selected for the second additional controls modeling scenario for AVS since the Department did not consider any remaining control options to be economically reasonable for evaluation.

The results for the visibility modeling evaluation of the 2028 first potential additional controls scenarios are addressed in Section 6.1.1. The first scenario resulted in a projected improvement of 0.08 deciviews at TRNP and 0.1 deciviews at LWA on the IMRPOVE MIDs. Again, the first scenario also includes reductions from Coyote Station (Section 5.2.1). The visibility improvements modeled for the first scenario are not considered significant since the improvements are smaller than what is perceptible by an unaided human eye.

Since the modeling has indicated no expected significant change in visibility (Section 6.1.1) and TRNP and LWA are projected to achieve the adjusted uniform rate of progress required by 2028 (Section 3.1 and 6.1.1), the Department does not believe additional SO₂ controls at AVS should be required during this planning period. The Department will re-evaluate this decision during the 2025 progress report.

5.2.3 Basin Electric Power Cooperative – Leland Olds Station

Basin Electric Power Cooperative – Leland Olds Station (LOS) is a two-unit electrical generating station. Unit 1 and Unit 2 both primarily fire lignite with a small amount of subbituminous coal combusted. Unit 1 began commercial operation in 1966 and is a Babcock & Wilcox opposed wall-fired boiler that has the capacity to produce approximately 216 Megawatts (MW) per hour of electricity. Unit 2 began commercial operation in 1975 and is a Babcock & Wilcox cyclone-fired boiler that has the capacity to produce approximately 440 MW per hour of electricity. LOS is located on the banks of the Missouri River in eastern Mercer County, approximately four miles southeast of the town of Stanton, North Dakota. LOS receives lignite from the Coteau Properties Freedom Mine, which is located approximately thirty miles west of LOS.

As documented in Table 35, LOS Unit 1 has a Q/d of 42 and LOS Unit 2 has a Q/d of 63. Therefore, the Department sent a letter to Basin on May 2, 2018, requesting an evaluation of additional potential control measures.⁹⁶ The letter required that Basin's report be submitted to the Department on or before January 31, 2019. Basin's original report was submitted to the Department on January 31, 2019.⁹⁷ The Department provided comments to address areas of concern in Basin's report on April 15 and April 22, 2019.⁹⁸ Basin submitted a response to the Department's comments on July 26, 2019.⁹⁹ On November 20, 2019, Basin submitted an update to the steam costs that were used to develop the operating costs for the technically feasible NO_x reduction technologies.¹⁰⁰ A copy of each submittal by Basin LOS can be found in Appendix B.3.b.

The Department evaluated the information submitted by Basin and conducted its own independent four factor analysis to determine the appropriate control requirements for LOS. Based on the Department's evaluation of all sources of information, future operations and emissions profiles are expected to remain

⁹⁶ Appendix B.3.a.

⁹⁷ Appendix B.3.b.

⁹⁸ Appendix B.3.c.

⁹⁹ Appendix B.3.c.

¹⁰⁰ Appendix B.3.b., PDF page 504.

consistent with current conditions. Additionally, the control cost estimations presented in the Department's four-factor analysis are accurate and consistent with Department experience based on past analysis of source control costs. The Department's four-factor analysis of Basin LOS's additional control measures evaluation can be found in Appendix A.3.

During the first round of regional haze, the Department determined that BART for LOS Unit 1 and Unit 2 included new wet limestone flue gas desulfurization (WFGD) for SO₂ control and selective non-catalytic reduction (SNCR) and separated overfire (SOFA) air for NO_x control.¹⁰¹ The Department's consideration and application of the four factors (as set forth in Appendix A.3) are summarized as follows. Time necessary for compliance was determined not to be significant enough to discount any control options. Energy and non-air quality environmental impacts were determined not to be significant enough to eliminate any of the control options. Remaining useful life was determined by the Department to not eliminate any control options. Therefore, cost of compliance was most heavily considered by the Department in selection of additional controls for modeling review and to determine if these controls are appropriate and necessary to demonstrate reasonable progress. The Department's the four-factor analysis confirmed that these BART controls operate effectively, and the Department has no reason to believe effective operation of the BART controls will change in the future. Therefore, no additional measures were selected for the modeling evaluation and the Department does not believe additional controls are warranted during this planning period. The Department will re-evaluate this decision during the 2025 progress report.

5.2.4 Coal Creek Station

Note: The regional haze analysis for Coal Creek Station has been separated into two sections due to the unresolved BART approval from the first round. Section 8 contains a NO_x BART determination relating to the unresolved NO_x BART approval and also serves as a reasonable progress determination for round 2. This section contains a reasonable progress analysis for additional SO₂ measures for round 2 of the RHR. This section also contains the emissions information specific to current and future expected operations which were utilized in the modeling evaluations for Round 2 planning.

Coal Creek Station (CCS) is a two-unit, approximately 1,200 gross MW mine-mouth power plant consisting primarily of two steam generators and associated coal and ash handling systems. Unit 1 and Unit 2 are identical Combustion Engineering boilers firing pulverized lignite coal tangentially. Unit 1 has a heat input capacity of 6,015 MMBtu per hr. Unit 2 has a heat input capacity of 6,022 MMBtu per hr. Unit 1 began commercial operation in 1979. Unit 2 began commercial operation in 1980. The facility is located in south central McLean County about five miles south of the town of Underwood, North Dakota and three miles west of US Highway 83. CCS receives lignite coal from the Falkirk Mine that is operated by the Falkirk Mining Company, a subsidiary of the North American Coal Corporation.

As documented in Table 35, Coal Creek Unit 1 has a Q/d of 75 and Coal Creek Unit 2 has a Q/d of 63. Therefore, the Department sent a letter to Great River Energy on May 2, 2018 requesting an evaluation

¹⁰¹ North Dakota State Implementation Plan for Regional Haze, March 3, 2010, Appendix B.4.

of additional potential control measures.¹⁰² The letter required that Great River Energy's report be submitted to the Department on or before January 31, 2019. The Department emailed Great River Energy on December 18, 2018, to inform Great River Energy that they should focus on completing an updated BART analysis for the first round of Regional Haze planning.¹⁰³ On September 12, 2019, Great River Energy submitted an updated BART analysis associated with the first round of Regional Haze planning.¹⁰⁴

5.2.4.1 CCS SO₂ Emissions

After submission of the updated NO_x BART analysis (Section 8), Great River Energy CCS completed an evaluation of additional potential control measures. CCS submitted the report for the second round of Regional Haze planning on December 23, 2019.¹⁰⁵ Both SO₂ and NO_x were addressed in the submittal.

The Department evaluated the information submitted by CCS and conducted its own independent four factor analysis to determine the appropriate control requirements for CCS. Based on the Department's evaluation of all sources of information, future operations and SO₂ emissions profiles are expected to remain consistent with current conditions. Additionally, the control cost estimations presented in the Department's four-factor analysis are accurate and consistent with Department experience based on past analysis of source control costs. The Department's four-factor analysis of CCS's additional control measures evaluation can be found in Appendix A.4.

As outlined in CCS's submittal and as requested, the Department evaluated lower allowable operating limits (near a rate of 0.10 lb SO₂ per MMBtu). This resulted in the Department including 700 tons of SO₂ reductions in the modeling evaluation for 2028. Due to the pending change in ownership the improvements are no longer being considered with this SIP revision.¹⁰⁶ These potential improvements were voluntary and are not necessary since the Department believes the existing level of SO₂ controls operate effectively. Review of the four-factor analysis confirms this position.

5.2.4.2 CCS Emissions for WRAP Modeling for Round 2 Planning

CCS completed installation of additional low-NO_x combustion controls on Unit 1 in 2020. These controls result in an anticipated reduction of approximately 1,000 tons of NO_x per year, details provided in Section 8. These controls were not included in the 2028OTB projected emissions as the Department was not aware of this project when the 2028OTB emissions modeling data was submitted to WRAP. However, the 1,000 tons NO_x per year reduction was included in the 2028PAC modeling since these controls will continue to operate in the future. Additionally, through operational improvements on the existing WFGD, Great River Energy anticipated they could reduce approximately 700 tons per year of SO₂. The 700 tons SO₂ per year reduction was included in the 2028PAC. For a description of the emissions inventory data and emissions nomenclature, see Section 4.

¹⁰⁴ Appendix B.4.b., PDF page 576.

¹⁰⁵ Appendix B.4.b., PDF page 1038

¹⁰⁶ See Section 8 for details on ownership change.

5.2.5 Minnkota – Milton R. Young Station

Minnkota Power Cooperative, Inc. – Milton R. Young Station (MRYS) is a two-unit electrical generating station. Unit 1 and Unit 2 are both Babcock & Wilcox cyclone-fired boilers fired on lignite coal. Unit 1 commenced commercial operation in 1970. Unit 1 has a turbine-generator nameplate rating of 257 megawatts (MW) and a nominal rated heat input capacity of 3,200 MMBtu per hour. Unit 2 commenced commercial operation in 1977. Unit 2 has a turbine-generator nameplate rating of 477 MW and a nominal rated heat input capacity of 6,300 MMBtu per hour. MRYS is located approximately five miles southeast of the town of Center, North Dakota. MRYS receives lignite from BNI Coal, Ltd's Center Mine, which is located adjacent to the facility.

As documented in Table 35, MRYS Unit 1 has a Q/d of 24 and MRYS Unit 2 has a Q/d of 43. Therefore, the Department sent a letter to Minnkota Power Cooperative, Inc. (Minnkota) on May 2, 2018, requesting an evaluation of additional potential control measures.¹⁰⁷ The letter required that Minnkota's report be submitted to the Department on or before January 31, 2019. Minnkota's original report was submitted to the Department on January 31, 2019.¹⁰⁸ The Department provided comments regarding areas of concern in the report to Minnkota on March 18, 2019.¹⁰⁹ Minnkota submitted a response to the Department's comments, along with a revised report, on May 29, 2019.¹¹⁰ A copy of each submittal by MRYS can be found in Appendix B.5.b.

The Department evaluated the information submitted by Minnkota and conducted its own independent four factor analysis to determine the appropriate control requirements for MRYS. Based on the Department's evaluation of all sources of information, future operations and emissions profiles are expected to remain consistent with current conditions. Additionally, the control cost estimations presented in the Department's four-factor analysis are accurate and consistent with Department experience based on past analysis of source control costs. The Department's four-factor analysis of Minnkota's additional control measures evaluation can be found in Appendix A.5.

MRYS Unit 1 and Unit 2 are equipped with Advanced Separated Over Fire Air (ASOFA) and SNCR for NO_x control. These were the BART controls selected in the first round of the Regional Haze program.¹¹¹ On April 24, 2006, Minnkota entered into a Consent Decree that required MRYS to install BACT for NO_x, which was determined to be SNCR along with the already installed ASOFA.^{112,113} MRYS Unit 1 is equipped with WFGD for SO₂ control. Unit 1 WFGD control technology was installed in 2011 as a result of the BART determination made in the first round of the Regional Haze program.¹¹⁴ MRYS Unit 2 is also equipped with

¹⁰⁷ Appendix B.5.a.

¹⁰⁸ Appendix B.5.b.

¹⁰⁹ Appendix B.5.c.

¹¹⁰ Appendix. B.5.b.

¹¹¹ North Dakota State Implementation Plan for Regional Haze, March 3, 2010, p. 74.

¹¹³ North Dakota State Implementation Plan for Regional Haze, March 3, 2010, Appendix B.4, p.16-19.

¹¹⁴ North Dakota State Implementation Plan for Regional Haze, March 3, 2010, p. 71.

WFGD for SO₂ control. Unit 2 WFGD control technology was installed prior to the first round of the Regional Haze program.

The Department's consideration and application of the four factors (as set forth in Appendix A.5) are summarized as follows. Time necessary for compliance was determined not to be significant enough to discount any control options. Energy and non-air quality environmental impacts were determined not to be significant enough to eliminate any of the control options. Remaining useful life was determined by the Department to not eliminate any control options. Therefore, cost of compliance was most heavily considered by the Department in selection of additional controls for modeling review and to determine if these controls are appropriate and necessary to demonstrate reasonable progress. The Department's four-factor analysis confirmed that these BART controls operate effectively, and the Department has no reason to believe effective operation of the BART controls will change in the future. Therefore, no additional controls were selected for the modeling evaluation and the Department does not believe additional controls are warranted during this planning period. The Department will re-evaluate the adequacy of this decision during the 2025 progress report.

5.2.6 Montana Dakota Utilities – Heskett Station

Montana Dakota Utilities – Heskett Station (Heskett) is a two-unit electrical generating station. Unit 1 is a 25 MW Riley Stoker boiler fired on lignite coal. Unit 1 went online in 1954 and has a rated heat input of 387 MMBtu per hour. Unit 2 is a 75 MW Babcock & Wilcox atmospheric fluidized bed boiler fired on lignite coal. Unit 2 went online in 1963 and has a rated heat input of 917 MMBtu per hour. Heskett is located in Mandan, North Dakota and receives lignite from the Dakota Westmoreland Mine south of Beulah, North Dakota.

As documented in Table 35, Heskett Unit 1 has a Q/d of 7 and Heskett Unit 2 has a Q/d of 16. Since the facility has a Q/d greater than 10, the Department sent a letter to Montana Dakota Utilities (MDU) on May 2, 2018, requesting an evaluation of potential additional control measures.¹¹⁵ The letter required that MDU's report be submitted to the Department on or before January 31, 2019. MDU submitted the report to the Department on January 31, 2019.¹¹⁶ A copy of the submittal by Heskett can be found in Appendix B.6.b.

On February 19, 2019, MDU submitted an official notification to the Department that MDU plans to retire Unit 1 and Unit 2 at Heskett around the end of 2021.¹¹⁷ MDU plans to replace Unit 1 and Unit 2 with a new natural gas unit in early 2023. The Department issued MDU a permit to construct for the new natural gas unit. The Department determined that it was not necessary to conduct a four-factor analysis due to the announced shutdown of the Unit 1 and Unit 2 at Heskett. A copy of the permit to construct issued for the new gas unit can be found in Appendix A.6. The permit to construct, APC-17983v1.0, requires the coal plant equipment to be removed or permanently decommissioned prior to commencement of the new gas turbine. The Department received notice on March 9, 2022, that Unit 1 and Unit 2 at Heskett station have

¹¹⁵ Appendix B.6.a.

¹¹⁶ Appendix B.6.b.

¹¹⁷ Appendix B.6.c.

been permanently retired and will undergo decommissioning. Unit 1 shut down February 25, 2022, and Unit 2 shut down on January 31, 2022.¹¹⁸

The Department included the emissions reductions from Heskett in this proposed SIP as a result of the retirement of Unit 1 and Unit 2. The shutdown of Unit 1 and Unit 2 will result in approximately 2,000 tons of SO₂ reductions and 900 tons of NO_x reductions and were included in the 2028 inventory projection.

5.2.7 Petro-Hunt, L.L.C. – Little Knife Gas Plant

Petro-Hunt, L.L.C. – Little Knife Gas Plant (LKGP) is comprised of numerous fuel gas combustion units, process equipment, tankage, flares, and a sulfur recovery process controlled by an incinerator. The major emissions source onsite is the 2-stage 2-bed Cold Bed Absorption (CBA) sulfur recovery unit (SRU) tail gas incinerator. The LKGP is located approximately 18 miles southwest of Killdeer, North Dakota in Billings County.

As documented in Table 35, the LKGP has a Q/d of 12. Therefore, the Department sent a letter to Petro-Hunt, L.L.C. (Petro-Hunt) on May 2, 2018, requesting an evaluation of additional control measures.¹¹⁹ The letter required that Petro-Hunt's report be submitted to the Department on or before January 31, 2019. Petro-Hunt submitted a response to the Department's request on November 29, 2018.¹²⁰ The Department responded to Petro-Hunt's submittal on December 5, 2018, indicating that Petro-Hunt's submittal did not adequately address the requirements of the Regional Haze program.¹²¹ Petro-Hunt submitted an updated report to the Department on January 25, 2019.¹²² A copy of each submittal by LKGP can be found in Appendix B.7.b.

The Department evaluated the information submitted by Petro-Hunt and conducted its own independent four factor analysis to determine the appropriate control requirements for LKGP. Based on the Department's evaluation of all sources of information, future operations and emissions profiles are expected to remain consistent with current conditions. Additionally, the control cost estimations presented in the Department's four-factor analysis are accurate and consistent with Department experience in evaluating source control costs. The Department's four-factor analysis of Petro-Hunt's additional control measures evaluation can be found in Appendix A.7.

For SO₂ control, LKGP operates a sulfur recovery unit (SRU) consisting of a two-stage Claus unit with cold bed absorption. The SRU recovers approximately 94% of the sulfur entering the unit. SO₂ emissions are the only significant pollutant emitted from the facility. Therefore, NO_x controls were not evaluated for this source. The Department's consideration and application of the four factors (as set forth in Appendix A.7) are summarized as follows. Time necessary for compliance was determined not to be significant enough to discount any control options. Energy and non-air quality environmental impacts were determined not to be significant enough to eliminate any of the control options. Remaining useful life was determined by

¹¹⁸ Appendix A.6.

¹¹⁹ Appendix B.7.a.

¹²⁰ Appendix B.7.c.

¹²¹ Appendix B.7.c.

¹²² Appendix B.7.b.

the Department to not eliminate any control options. Therefore, cost of compliance was most heavily considered by the Department in selection of additional controls for modeling review and to determine if these controls are appropriate and necessary to demonstrate reasonable progress. The Department's four-factor analysis confirms LKGP has effective controls already in place. Therefore, no additional controls for LKGP were selected to include in the first or second additional controls modeling scenario. Additionally, the magnitude of remaining SO₂ reductions available from this source is minimal when compared to a typical North Dakota coal fired EGU.¹²³ The Department will re-evaluate the adequacy of this decision during the 2025 progress report.

5.2.8 Hess Tioga Gas Plant, LLC – Tioga Gas Plant

Hess Tioga Gas Plant, LLC – Hess Tioga Gas Plant (TGP) is comprised of numerous boilers, heaters, compressor engines, turbines, storage tanks, process equipment, flares, and a sulfur recovery process controlled by an incinerator. Most of the emissions are sourced from the compressor engines and the amine gas sweetening unit (the SRU tail gas incinerator). Tioga is located just to the east of Tioga, North Dakota in Williams County.

As documented in Table 35, Tioga has a Q/d of 55. Therefore, the Department sent a letter to Hess Corporation (Hess) on May 18, 2018, requesting an evaluation of additional potential control measures.¹²⁴ The letter required that Hess's report be submitted to the Department on or before January 31, 2019. Hess's original report was submitted to the Department on December 20, 2018.¹²⁵ The Department provided comments to Hess regarding areas of concern in the report on January 16, 2019.¹²⁶ Hess submitted a revised report on March 13, 2019.¹²⁷ A copy of each submittal by TGP can be found in Appendix B.8.b.

The Department evaluated the information submitted by Hess and conducted its own independent four factor analysis to determine the appropriate control requirements for TGP. Based on the Department's evaluation of all sources of information, future operations and emissions profiles are expected to remain consistent with current conditions. Additionally, the control cost estimations presented in the Department's four-factor analysis are accurate and consistent with Department experience in evaluating source control costs. The Department's four-factor analysis of Hess's additional control measures evaluation can be found in Appendix A.8.

TGP operates a sulfur recovery unit (SRU) consisting of a two-stage Claus unit with cold bed absorption for SO₂ controls. The SRU recovers approximately 96% of the sulfur entering the unit. TGP has not recently installed any significant NO_x controls at the facility. The most significant source of NO_x emissions (91%) come from the operation of 1950's era compressor engines (Clark Engines). On January 10, 2022, the Department and Hess TGP entered into an administrative consent agreement, Case No. 21-169 APC, to remove the non-retrofitted Clark engines before July 1, 2024, and to remove the retrofitted Clark engines

¹²³ Representative emissions from Coyote, AVS, LOS, Coal Creek, and MRYS on a per unit basis.

¹²⁴ Appendix B.8.a.

¹²⁵ Appendix B.8.b.

¹²⁶ Appendix B.8.c.

¹²⁷ Appendix B.8.b.

from service before June 30, 2025.¹²⁸ This agreement will significantly reduce NO_x emissions from the facility. The Department's administrative consent agreement will ensure continued compliance with the 1-hour NO₂ NAAQS standards. This administrative consent agreement will also provide collateral benefits to visual air quality since emissions of NO_x will be significantly reduced. The 2028OTB emissions did not consider these reductions since they were not enforceable at the time the projections were provided and used in the various modeling exercises. The NO_x reductions from this agreement supersede the information addressed in the Department's NO_x four-factor analysis.

For regional haze purposes, based on the Department's SO₂ four-factor analysis and TGP having effective controls already in place, no additional SO₂ controls for the TGP were selected to include in the first or second additional controls modeling scenario. Of note, the magnitude of SO₂ reductions available from this source is minimal when compared to a typical North Dakota coal fired EGU.¹²⁹ The Department will re-evaluate the adequacy of this decision during the 2025 progress report.

5.2.9 Northern Border Compressor Station No. 4

Northern Border Pipeline Company – Compressor Station No. 4 (CS4) is a compressor station with the majority of emissions being sourced from a 20,000 horsepower simple cycle natural gas-fired combustion turbine (Unit CE1), which drives a natural gas compressor. The turbine is a Cooper-Rolls Model Coberra 2648S Avon. CS4 is located approximately nine miles west of Watford City, North Dakota in McKenzie County.

As documented in Table 35, Northern Border Pipeline Company (Northern Border) Unit CE1 has a Q/d of 9. Although Northern Border's CS4 had a Q/d below the threshold of 10, the Department sent a letter to Northern Border requesting an evaluation of additional control measures since CS4's Q/d was sufficiently close to the Q/d threshold and CS4 is located only 18 km from the nearest CIA. The Department sent a letter to Northern Border on May 2, 2018, requesting a report for CS4.¹³⁰ The letter required that Northern Border's report be submitted to the Department on or before January 31, 2019. Northern Border's original report was submitted to the Department on December 10, 2018.¹³¹ The Department submitted comments regarding areas of concern in the report to Northern Border on December 28, 2018.¹³² Northern Border submitted a response to the Department's comments on March 1, 2019.¹³³ A copy of each submittal by CS4 can be found in Appendix B.9.b.

The Department evaluated the information submitted by Northern Border and conducted its own independent four factor analysis to determine the appropriate control requirements for CS4. Based on the Department's evaluation of all sources of information, future operations and emissions profiles are expected to remain consistent with current conditions. Additionally, the control cost estimations presented in the Department's four-factor analysis are accurate and consistent with Department

¹²⁸ Appendix A.8

¹²⁹ Representative emissions from Coyote, AVS, LOS, Coal Creek, and MRYS on a per unit basis.

¹³⁰ Appendix B.9.a.

¹³¹ Appendix B.9.b.

¹³² Appendix B.9.c.

¹³³ Appendix B.9.b. and Appendix B.9.c.

experience in evaluating source control costs. The Department's four-factor analysis of CS4's additional control measures evaluation can be found in Appendix A.9.

CS4 has not recently installed any significant NO_x controls at the facility. The NO_x emissions come from the operation of a 20,000-horsepower simple cycle natural gas-fired combustion turbine. The Department's consideration and application of the four factors (as set forth in Appendix A.9) are summarized as follows. Time necessary for compliance was determined not to be significant enough to discount any control options. Energy and non-air quality environmental impacts were determined not to be significant enough to eliminate any of the control options. Remaining useful life was determined by the Department to not eliminate any control options. Therefore, cost of compliance was most heavily considered by the Department in selection of additional controls for modeling review and to determine if these controls are appropriate and necessary to demonstrate reasonable progress. The Department evaluated controls for this turbine but determined controls were not necessary for installation during this planning period due to excessive cost and limited expected reduction in mass-based emissions.

Based on the Department's four-factor analysis and conclusions presented above, no additional controls for CS4 were selected to include in the first or second additional controls modeling scenario. Additionally, the magnitude of NO_x reductions available from this source is minimal when compared to a typical North Dakota coal fired EGU.¹³⁴ The Department will re-evaluate the adequacy of this decision during the 2025 progress report.

5.2.10 Dakota Gasification Company – Great Plains Synfuels Plant

Dakota Gasification Company (DGC) – Great Plains Synfuels Plant (GPSP) is owned and operated by Basin Electric Power Cooperative (Basin). DGC is a for-profit subsidiary of Basin and produces synthetic natural gas, fertilizers, and other byproducts resulting from the gasification of lignite coal. GPSP also captures carbon dioxide, which is transported via pipeline to oil fields in Saskatchewan Canada. The GPSP is the only facility of its kind in the United States. The GPSP commenced operation in 1984. The GPSP consists of many emissions units and emissions points. The significant sources of NO_x and SO₂ emissions include:

- Three Riley boilers each rated at 763 MMBtu per hour
- Two superheaters each rated at 169 MMBtu per hour
- One package boiler rated at 318 Mmbtu per hour
- The main flare and the start-up flare

The DGC GPSP is located approximately six miles northwest of the town of Beulah, North Dakota in Mercer County. The GPSP receives lignite coal from the Coteau Properties Freedom Mine located approximately two miles north of the GPSP. Coal which is too fine for gasification is sent back to the Antelope Valley Station (AVS) electrical generating utility (EGU).

As is documented in Table 35, the DGC GPSP has a Q/d of 61. Therefore, the Department sent a letter to DGC on May 2, 2018, requesting an evaluation of additional control measures based on the four factors

¹³⁴ Representative emissions from Coyote, AVS, LOS, Coal Creek, and MRYS on a per unit basis.

for the GPSP.¹³⁵ The letter required that DGC's report be submitted to the Department on or before January 31, 2019. DGC's report was submitted to the Department on January 31, 2019.¹³⁶ The Department found no areas of concern in the report received from DGC. A copy of the submittal by DGC can be found in Appendix B.10.b.

The Department evaluated the information submitted by DGC and conducted its own independent four factor analysis to determine the appropriate control requirements for GPSP. Based on the Department's evaluation of all sources of information, future operations and emissions profiles are expected to remain consistent with current conditions. Additionally, the control cost estimations presented in the Department's four-factor analysis are accurate and consistent with Department experience in evaluating source control costs. The Department's four-factor analysis and determination of GPSP's additional control measures evaluation can be found in Appendix A.10.

For SO₂ control, GPSP operates a WFGD unit to control emissions from the main stack. The WFGD unit removes approximately 97% of the SO₂ from the flue gas stream. GPSP has not recently installed any SO₂ controls or made any significant modification to the WFGD unit. GPSP has not installed any add-on NO_x controls at the facility. The most significant source of NO_x emissions (94%) comes from the main stack. The main stack receives flue gas from Riley boilers and superheaters. NO_x controls were evaluated for the Riley boilers and superheaters, none were determined to be technically feasible during this planning period. The Department's determination from its four-factor analysis are summarized as follows. Time necessary for compliance was determined not to be significant enough to discount any control options. Energy and non-air quality environmental impacts were determined not to be significant enough to eliminate any of the control options. Remaining useful life was determined by the Department to not eliminate any control options. Cost of compliance was considered in selection of additional controls for modeling review and to determine if these controls are appropriate and necessary to demonstrate reasonable progress. However, the Department's four-factor analysis confirmed that GPSP's controls operate effectively. Therefore, no additional measures were selected for the modeling evaluation and the Department does not believe additional controls are warranted during this planning period. The Department will re-evaluate the adequacy of this decision during the 2025 progress report.

DGC GPSP is currently evaluating the viability of discontinuing the coal gasification process and replacing it with a primary natural gas reformer for economic reasons. DGC GPSP incurred net losses of \$70.5 million in 2019 and has recorded a loss of \$89.5 million in the first nine months of 2020.¹³⁷ Eliminating the coal gasification process would significantly lower the NO_x and SO₂ emissions from this facility, as the gasification process provides much of the fuel consumed in the Riley boilers and the combustion of these fuels results in a significant portion of the facilities baseline emissions.

5.2.11 North Dakota Upstream Oil and Gas Development (Area Sources)

In addition to the point sources reviewed in Table 35, the Department considered the impacts to visibility from the upstream oil and gas development in North Dakota. Much of North Dakota's oil and gas production occurs in the western third of the state, which is the same geographical area of both of North Dakota CIAs.

A Q/D type analysis does not work well for oil exploration or production facilities. Unlike point sources which can have large emissions from a single stack, upstream oil and gas consists of many small sources. These individual facilities generally have very low SO₂ and NO_x emissions, making an individual facility four factor analysis unnecessary. However, when all facilities' emissions are aggregated (entire source group), they become significant enough to warrant evaluation of the source group. The Q/D analysis in Section 5.1.2 includes the larger compressor stations and natural gas processing plants (sources subject to Title V). North Dakota also permits minor oil and gas sources including small compressor stations (greater than 500 hp), natural gas processing plants, and tank batteries. The Q/D analysis indicates that only the larger facilities (i.e. larger Title V sources) have a potential impact on visibility in North Dakota CIAs. SO₂ emissions from future oil and gas activities are not a concern because most new oil and gas production is from the Bakken formation which contains sweet oil and gas with very low sulfur content. In addition, all future engines are required by Federal rule to use ultra-low sulfur gasoline and diesel fuel (Section 5.3.1.2). Therefore, NO_x emissions are the primary concern. NO_x emissions occur from vehicles, drilling rig engines, glycol dehydrators, flares, compressor engines, and other combustion sources. Stationary engines are subject to several New Source Performance Standards (NSPS) and Maximum Achievable Control Technology (MACT) standards which help limit NO_x emissions. Emissions from upstream oil and gas activity are included in Section 4.3.1. These emissions were developed by the WRAP Oil and Gas Workgroup with input from the Department.¹³⁸

Following the emissions inventory work, the WRAP Oil and Gas Workgroup developed a memorandum providing information on potential additional controls strategies for oil and gas emission sources.¹³⁹ The analysis focused on stationary oil and gas emission sources (e.g. lift engines and flares) and did not include mobile sources (e.g. drill rigs or hydraulic fracturing engines). The Department does not have regulatory authority over mobile sources, therefore, these sources were not considered in developing this SIP revision. Drill rigs and hydraulic fracturing engines account for 28% (~16,000 of ~57,500 tons) of the total upstream NO_x emissions. Sources within the states control, such as, well site engines, wellsite heaters and boilers, and flaring accounts for the remaining 72% of nonpoint NO_x emissions. Wellsite engines, flaring, and wellsite heaters account for 50%, 19%, and 3% of the NO_x emissions, respectively.¹⁴⁰ Wellsite engines and flaring are addressed in the Sections 5.2.11.1 and 5.2.11.2, due to the small emissions from wellsite heaters, these will not be evaluated during this planning period.

¹³⁸ Additional details available at: <https://www.wrapair2.org/ogwg.aspx> (Last visited December 28, 2020)

¹³⁹ Available at: https://www.wrapair2.org/pdf/WRAP_OGWG_ARCS_Memo_23Mar2020.pdf (Last visited June 14, 2021)

¹⁴⁰ Available at: https://www.wrapair2.org/pdf/WRAP_OGWG_ARCS_Memo_23Mar2020.pdf (last visited June 14, 2021)

5.2.11.1 Wellsite Engines

Wellsite engines are used to extract oil and gas from the well. North Dakota has roughly 15,000 active operating wells. These 15,000 wells have a projected emissions of 29,000 tons of NO_x. Averaged across the total wellsite's in North Dakota, this is less than 2 tons of NO_x per well. The Department determined that individual engine controls are not reasonable during this planning period. This determination was based on the limited emissions footprint from any single wellsite and relatively small contribution to visibility impairment from this sector.

5.2.11.2 Associated Gas Flaring

Flaring in North Dakota happens in two ways, high and low pressure. High pressure flaring contributes significantly more to total flared volume. High pressure flaring primarily occurs when there is no infrastructure (e.g. pipeline) available to transport the gas produced offsite or when the infrastructure available is at capacity. Low pressure flaring occurs when oil stored onsite releases light hydrocarbons which are routed to a flare. The Department believes the most practical and effective way to reduce visibility impairing emissions from this sector is by reducing the volume of high pressure gas flared at the wells. Reducing the volume of high pressure gas flared is accomplished by the continued development of the infrastructure needed to handle the gas production associated with oil well development. Pipelines, compressor stations, and gas plants are continuing to be constructed and expanded in effort to reduce the flared gas amounts. North Dakota Industrial Commission Order 24665 sets policy goals to increase the volume of captured gas and reduce the percentage of flared gas. The order also incentivizes the investment in gas capture infrastructure.¹⁴¹ A capture goal of 91% beginning in November 1, 2020 is a stated goal of the policy. As of October 2020, a 93% gas capture rate was achieved statewide.¹⁴² Continuing to meet the capture goals set by the policy will be beneficial to reducing the visibility impact these sources have on North Dakota CIAs.

A breakdown of the amount of gas produced, sold, flared, and the percent of gas flared is displayed in Figure 43. This information is updated through December 2020. The average monthly flared percent in 2020 was 10%, with September, October, and November each below 8%. Followed by December achieving the lowest percent of flared gas at 6.4% since significant development of the Bakken formation.¹⁴³

Figure 43: Volume of Gas Produced, Sold, Flared, and Flared Percent from 2000–2020.

5.2.11.3 Upstream Oil and Gas Conclusion

Collectively, emissions from wellsite engines in North Dakota are the largest source of NO_x emission from upstream oil and gas development. Individually, emissions from any one wellsite engine are minor, making any single sites contribution to visibility impairment insignificant. North Dakota oil producers are currently meeting the gas capture goals put in place by the North Dakota Industrial Commission. With increased infrastructure being continually developed in North Dakota, it is reasonable to expect this trend to continue. Finally, North Dakota is currently making progress to improve visibility, and this is expected to continue through this planning period. For these reasons, the Department does not believe it is reasonable to implement additional controls on sources in this sector during this planning period.

The Department will continue to monitor the development of the Bakken Formation and the impacts to North Dakota's CIA visibility progression and provide an update in the 2025 progress report.

5.3 §51.308(f)(2)(iv) – Additional Factors in Development of Long-Term Strategy

40 CFR 51.308(f) details that five additional factors must be considered and described within the periodic comprehensive revisions of state implementation plans for regional haze in terms of development of the long-term strategy:

- (A) Emission reductions due to ongoing air pollution control programs, including measures to address reasonably attributable visibility impairment;
- (B) Measures to mitigate the impacts of construction activities;

- (C) Source retirement and replacement schedules;
- (D) Basic smoke management practices for prescribed fire used for agricultural and wildland vegetation management purposes and smoke management programs; and
- (E) The anticipated net effect on visibility due to projected changes in point, area, and mobile source emissions over the period addressed by the long-term strategy.

These five additional factors are discussed in Sections 5.3.1 through 5.3.5.

5.3.1 §51.308(f)(2)(iv)(A) – Emission Reductions Due to Ongoing Air Pollution Control Programs

Air pollution control programs that assist in reducing emissions and help to achieve reasonable progress toward the national visibility goal include state and federal programs, which are both detailed below. In addition, NDDEQ takes enforcement actions against entities found to be in violation of the air pollution control program requirements. Enforcement actions taken by NDDEQ since 2000 are displayed in Figure 44.

Figure 44: NDDEQ Air Quality Enforcement Actions from 2000 through June 30, 2021.

Figure 44 shows that NDDEQ has increased the number of enforcement cases since the year 2000, with a more notable uptick starting in 2012. Many of these enforcement actions since 2012 were directed toward the oil and gas development in North Dakota.

It should be noted that unless specifically stated in the text, all reference to enforcements, existing rules or emission control programs are intended only to provide information about various aspects of the

program described and are neither being submitted to EPA for approval nor being incorporated into the SIP as Federally enforceable measures if they have not previously been incorporated.

This SIP is North Dakota's comprehensive visibility plan. It addresses all aspects of North Dakota's visibility improvement program.

This SIP Revision documents those programs, rules, processes, and controls deemed appropriate as measures needed to reduce regional haze and protect visibility in North Dakota in order to meet the RPGs established in the RHR and the CAA.

5.3.1.1 State Regulations from the North Dakota Administrative Code (NDAC)

North Dakota has state emission control programs and rules that focus on the protection of visibility. In addition, North Dakota has state emission control programs and rules that were not specifically written to address visibility impairment but still work to improve and protect visibility in CIAs by controlling the emissions of pollutants that cause or contribute to visibility impairment. Both programs that specifically address visibility impairment and programs not specific to visibility impairment that still improve visibility are detailed in Sections 5.3.1.1.1 through 5.3.1.1.17.

5.3.1.1.1 NDAC 33.1-15-02: Ambient Air quality Standards

Chapter 33.1-15-02 aims to maintain the current quality of the air within the boundaries of North Dakota.¹⁴⁴ Specific to the protection of visibility, Section 33.1-15-02-03 states in part:

"In keeping with the purpose of these ambient air quality standards, the quality should be such that:

- 4. Visibility will be protected.*
- 7. Natural scenery will not be obscured."*

5.3.1.1.2 NDAC 33.1-15-03: Restriction of Emission of Visible Air Contaminants

Chapter 33.1-15-03 restricts the degree of opacity that can be discharged into the ambient air from both new and existing installations.¹⁴⁵ The restriction of opacity, or visible emissions, has a direct impact on visibility.

5.3.1.1.3 NDAC 33.1-15-04: Open Burning Restrictions

Chapter 33.1-15-04 aims to maintain air quality by restricting the types of material that may be burned in North Dakota.¹⁴⁶ Section 33.1-15-04-02 states in part:

- "2. The following conditions apply to all types of permissible burning listed in subsection 1.
 - h. Except in an emergency, burning may not be conducted in such proximity of any Class I area, as defined in chapter 33.1-15-15, that the ambient air of such area is adversely impacted.**

¹⁴⁴ Available at: <https://www.legis.nd.gov/information/acdata/pdf/33.1-15-02.pdf?20150602082326>

¹⁴⁵ Available at: <https://www.legis.nd.gov/information/acdata/pdf/33.1-15-03.pdf?20150202141005>

¹⁴⁶ Available at: <https://www.legis.nd.gov/information/acdata/pdf/33.1-15-04.pdf?20150202141022>

- i. *Except in an emergency, the visibility of any Class I area cannot be adversely impacted as defined in chapter 33.1-15-19.”*

5.3.1.1.4 NDAC 33.1-15-05: Particulate Matter Restricted

Chapter 33.1-15-05 aims to maintain air quality through the restriction of particulate matter.¹⁴⁷ Particulate matter has a direct impact on visibility impairment. Therefore, Chapter 33.1-15-05 has a direct impact on maintaining visibility in North Dakota.

5.3.1.1.5 NDAC 33.1-15-06: Emissions of Sulfur Compounds Restricted

Chapter 33.1-15-06 aims to maintain air quality through the restriction of sulfur compounds.¹⁴⁸ SO₂ and other sulfur oxides can react with other compounds in the atmosphere to form fine particles that impair visibility. Therefore, Chapter 33.1-15-06 has a direct impact on maintaining visibility in North Dakota.

5.3.1.1.6 NDAC 33.1-15-07: Control of Organic Compounds Emissions

Chapter 33.1-15-07 aims to maintain air quality through the control of organic compounds.¹⁴⁹ Volatile organic compounds (VOCs) can react with nitrogen oxides to form smog, which reduces visibility. Therefore, Chapter 33.1-15-07 has a direct impact on maintaining visibility in North Dakota.

5.3.1.1.7 NDAC 33.1-15-08: Control of Air Pollution from Vehicles and Other Internal Combustion Engines

Chapter 33.1-15-08 aims to maintain air quality through the control of vehicles and other internal combustion engines.¹⁵⁰ Section 33.1-15-08-01 states:

“No person shall operate, or cause to be operated, any internal combustion engine which emits from any source any unreasonable and excessive smoke, obnoxious or noxious gases, fumes or vapor.”

The proper operation of internal combustion engines has a direct impact on maintaining visibility in North Dakota.

5.3.1.1.8 NDAC 33.1-15-12: Standards of Performance for New Stationary Sources

North Dakota has adopted many subparts and appendices of 40 CFR 60.¹⁵¹ Many of these subparts require compliance with performance standards which inherently controls pollutants that contribute to visibility impairment. For example, any subpart which restricts the amount of NO_x, SO₂, VOC, or PM would also have a beneficial impact on reducing visibility impairment. The subparts adopted by North Dakota are contained within Chapter 33.1-15-12.

¹⁴⁹ Available at: <https://www.legis.nd.gov/information/acdata/pdf/33.1-15-07.pdf?20150202141202>

¹⁵⁰ Available at: <https://www.legis.nd.gov/information/acdata/pdf/33.1-15-08.pdf?20150202141225>

¹⁵¹ Available at: <https://www.legis.nd.gov/information/acdata/pdf/33.1-15-12.pdf?20150202141441>

5.3.1.1.9 NDAC 33.1-15-13: Emission Standards for Hazardous Air Pollutants

North Dakota has adopted multiple subparts and appendices of 40 CFR 61.¹⁵² All subparts and appendices adopted by North Dakota are contained within Chapter 33.1-15-13. The subparts adopted by North Dakota which require the control of pollutants that contribute to visibility impairment include:

- Subpart J – National Emission Standard for Equipment Leaks (Fugitive Emission Sources) of Benzene
- Subpart V – National Emission Standard for Equipment Leaks (Fugitive Emission Sources)
- Subpart FF – National Emission Standard for Benzene Waste Operations

5.3.1.1.10 NDAC 33.1-15-14: Designated Air Contaminant Sources, Permit to Construct, Minor Source Permit to Operate, Title V Permit to Operate

North Dakota operates a permitting program that evaluates new construction projects for their impact on air quality.¹⁵³ Once a permit to construct is issued, a facility may be built. Once construction is completed, a facility inspection is performed to ensure construction was in line with the permit to construct and then an appropriate permit to operate is issued. Non-Title V sources receive a Department issued minor source permit to operate after construction permit inspection. Title V sources must apply for a Title V permit within a year of completed construction and initial operation. The primary goal of the permitting program is to maintain compliance with both federal and state regulations. Although the primary goal of the permitting program is not to protect visibility, maintaining compliance with federal and state regulations inherently helps to protect visibility.

5.3.1.1.11 NDAC 33.1-15-15: Prevention of Significant Deterioration of Air Quality

Chapter 33.1-15-15 requires that a visibility analysis be prepared in accordance with Chapter 33.1-15-19 for any permit to construct that meets the requirements of the prevention of significant deterioration program.¹⁵⁴ Since one of the primary goals of the Prevention of Significant Deterioration (PSD) program is to preserve, protect, and enhance the air quality in national parks and national wilderness areas, Chapter 33.1-15-15 has a direct impact on maintaining visibility in North Dakota.

5.3.1.1.12 NDAC 33.1-15-17: Restriction of Fugitive Emissions

Chapter 33.1-15-17 restricts the release of fugitive emissions, which is inherently designed to maintain both air quality and visibility.¹⁵⁵ Section 33.1-15-17-02 states in part:

“No person shall emit or cause to be emitted into the ambient air from any source of fugitive emissions as specified in section 33.1-15-17-01 any particulate which:

5. *Would have an adverse impact on visibility, as defined in chapter 33.1-15-19, on any class I federal area.”*

¹⁵² Available at: <https://www.legis.nd.gov/information/acdata/pdf/33.1-15-13.pdf?20150202141536>

¹⁵³ Available at: <https://www.legis.nd.gov/information/acdata/pdf/33.1-15-14.pdf?20150202141623>

¹⁵⁴ Available at: <https://www.legis.nd.gov/information/acdata/pdf/33.1-15-15.pdf?20150202141650>

¹⁵⁵ Available at: <https://www.legis.nd.gov/information/acdata/pdf/33.1-15-17.pdf?20150202142045>

5.3.1.1.13 NDAC 33.1-15-19: Visibility Protection

The federal visibility regulations (40 CFR 51, Subpart P) detail a two-phased process to determine existing impairment in each CIA, how to remedy such impairment, and how to establish goals to restore visibility to natural conditions by the year 2064 in each CIA. Phase 1 of the visibility regulations addresses impacts in CIAs by establishing a process to evaluate source specific visibility impacts, or plume blight, from individual sources or small groups of sources. Part of that process relates to the evaluation of sources prior to construction through the prevention of significant deterioration (PSD) permit program for major stationary sources (Chapter 33.1-15-15). The plume blight part of the Phase 1 program also allows for the evaluation, and possible control, of reasonably attributable visibility impairment (RAVI) from existing sources. The Phase 1 program addresses major source PSD permitting, source specific haze and plume blight aspects of visibility impairment. Chapter 33.1-15-19¹⁵⁶, in conjunction with Chapters 33.1-15-12, 33.1-15-14, and 33.1-15-15, make up North Dakota's SIP for Phase 1 of the visibility program, which was approved by the EPA and has an effective date of October 1, 1987. North Dakota's RAVI monitory strategy can be found in Section 6.6. The existing RAVI program, with the existing permitting and emissions rules listed in this section are compatible with those needed for regional haze and no revisions are needed or planned at this time.

5.3.1.1.14 NDAC 33.1-15-20: Control of Emissions from Oil and Gas Well Production Facilities

Chapter 33.1-15-20 includes requirements for the control of emissions from oil and gas well production facilities.¹⁵⁷ Most of the oil and gas production in North Dakota is contained within the western third of the state, which is also where North Dakota's CIAs are located. Therefore, emissions from oil and gas well production facilities in North Dakota may have an impact on visibility in North Dakota's CIAs. Although many of the oil and gas well production facilities in North Dakota do not emit significant amounts of pollution from any single source, the number of sources have increased over time (Section 5.2.11). NDAC Section 33.1-15-20-03 details the applicability and source information requirements of oil and gas well production facilities that may be subject to the prevention of significant deterioration:

"Any oil or gas well production facility that is a major stationary source or a major modification as defined in chapter 33.1-15-15, shall comply with the permitting requirements of chapter 33.1-15-15."

5.3.1.1.15 NDAC 33.1-15-21: Acid Rain Program

Chapter 33.1-15-21 details North Dakota's plan to control the pollutants that lead to the production of acid rain.¹⁵⁸ Since the acid rain program was first developed at the federal level, details regarding the impact of this program are covered in Section 5.3.1.2.3.

¹⁵⁶ Available at: <https://www.legis.nd.gov/information/acdata/pdf/33.1-15-19.pdf?20150202142145>

¹⁵⁷ Available at: <https://www.legis.nd.gov/information/acdata/pdf/33.1-15-20.pdf?20150202142208>

¹⁵⁸ Available at: <https://www.legis.nd.gov/information/acdata/pdf/33.1-15-21.pdf?20150202142230>

5.3.1.1.16 NDAC 33.1-15-22: Emissions Standards for Hazardous Air Pollutants for Source Categories

North Dakota has adopted many subparts and appendices of 40 CFR 63. Many subparts and appendices require the control pollutants that directly or indirectly contribute to visibility impairment. The subparts adopted by North Dakota are contained within Chapter 33.1-15-22.¹⁵⁹

5.3.1.1.17 NDAC 33.1-15-25: Regional Haze Requirements

Chapter 33.1-15-25 has an effective date of January 1, 2019¹⁶⁰ and implements the BART provisions of the federal RHR.¹⁶¹ A revision was needed to address the reasonable progress requirements for round 2 and future planning periods. This amendment took effect on July 1, 2020.

5.3.1.2 Federal Programs

The EPA has several existing emission control programs and rules that do not specifically address visibility impairment. However, the programs control the emission of pollutants that cause or contribute to visibility impairment in North Dakota. Therefore, these programs have an impact on North Dakota's CIAs. These programs are described in the following sections.

5.3.1.2.1 Volkswagen Environmental Mitigation Trust

On October 25, 2016, a Partial Settlement and Consent Decree was finalized between the United States Department of Justice and the Volkswagen Corporation (VW) regarding the installation and use of emissions testing defeat devices in over 500,000 VW vehicles sold and operated in the United States beginning in 2009. These devices violated the federal Clean Air Act and increased air emissions of the pollutant nitrogen oxide (NO_x).

An environmental mitigation trust (trust) has been established as part of the consent decree to provide funds to the states to mitigate the negative air quality impacts of the violations. North Dakota's total share of the trust is \$8.1 million. The trust establishes a process for states to receive the funds and develop environmental mitigation plans. The trust also identified the mitigation projects that are eligible for funding.

North Dakota has set up an application process to fund projects that reduce NO_x emissions. North Dakota recently finished the second round of funding for the VW Settlement funding program. Nine buses and five trucks were funded to be replaced by newer vehicles in the first round. Fifteen buses and ten trucks were funded to be replaced by newer vehicles in the second round. As a requirement of the trust, the older vehicle must be scrapped. North Dakota also funded the installation of electric vehicle charging stations at 17 sites during the first round of funding.

More information and future updates on North Dakota's funding for the trust can be found at <https://www.vwenvironmentalmitigationtrust.com/state-trust/north-dakota>.

¹⁵⁹ Available at: <https://www.legis.nd.gov/information/acdata/pdf/33.1-15-22.pdf?20150202142330>

¹⁶⁰ Original effective date was January 1, 2007. Date was revised upon transition from the Department of Environmental Health Section to the Department of Environmental Quality. See Footnote 8.

¹⁶¹ Available at: <https://www.legis.nd.gov/information/acdata/pdf/33.1-15-25.pdf?20150202142452>

5.3.1.2.2 EPA's Diesel Emissions Reduction Act (DERA)

The EPA allocates funds within the DERA program to individual states each year to help fund the replacement of older diesel-powered vehicles that do not operate as efficiently as newer engines. The amount of funds varies yearly and the program provides up to 25% of the cost of the replacement vehicle. The DERA program began in 2008. Emission reductions since the initiation of the program are included in Table 36.

Table 36: Emission Reductions since initiation of DERA program

Year	Number of Vehicles Funded	NO _x (tons)	PM (tons)	VOC (tons)	CO (tons)
2008	8	21.9	1.0	1.5	6.2
2009	2	6.4	0.2	0.2	1.2
2010	16	39.9	2.0	2.8	11.8
2011	8	15.7	0.7	1.0	4.2
2012	5	11.8	0.6	1.0	3.9
2013	5	10.7	0.5	0.9	3.9
2014	4	1.7	0.1	0.3	0.6
2015	6	2.1	0.2	0.4	0.9
2016	8	2.4	0.2	0.4	1.0
2017	9	2.0	0.1	0.2	0.6
2018	12	2.6	0.2	0.4	1.1
Total	83	117.3	5.6	8.9	35.4

Emission reductions were largest at the start of the DERA program when the least efficient vehicles were being replaced within the program. The decrease in emission reductions in the more recent years of the program illustrate the success of the early years of the program and the improvements in vehicle efficiencies as a result of more stringent national vehicle emission standards detailed in Section 5.3.1.2.7. In 2019, ten vehicles were funded for replacement. At the time of this SIP revision, not all these vehicle replacements have been completed, and therefore, were not included in Table 36. Once all ten replacements are completed, the NO_x reductions are anticipated to be between 2.0 and 2.6 tons.

5.3.1.2.3 Acid Rain Program (ARP)

In addition to being the two primary emissions contributing to visibility impairment in North Dakota, SO₂ and NO_x are the two primary precursors of acid rain. The Acid Rain Program (ARP) was established under Title IV of the 1990 Clean Air Act Amendments and requires significant reductions in SO₂ and NO_x emissions from the power sector.¹⁶² The ARP was released in two phases, with Phase I beginning in 1995 and Phase II beginning in 2000. The ARP set a goal of reducing annual SO₂ emissions by 10 million tons below 1980 levels. The ARP also set a goal of a two-million-ton reduction in NO_x emissions below 1980 levels by the year 2000. Although the ARP is not solely focused on SO₂ and NO_x reductions within North Dakota, SO₂ and NO_x reductions throughout the United States also benefit visibility within North Dakota CIAs, since air is not contained within state boundaries. Significant reductions have occurred throughout the United States, with the majority of SO₂ and NO_x reductions achieved in the eastern and southeastern

¹⁶² Available at: <https://www.epa.gov/acidrain/acid-rain-program> (Last visited December 28, 2020)

portion of the United States, where much of the affected power sector is located. When winds are from an easterly or southeasterly direction, North Dakota CIAs will see some benefit. Figure 45 shows NO_x emissions across the continental United States in 1990 relative to 2019. Figure 46 shows the same for SO₂ emissions. It should be noted that Figure 45 and Figure 46 illustrate total NO_x and SO₂ emission reductions across the continental United States. Although the ARP and the CSAPR have resulted in significant reductions in NO_x and SO₂ emissions, other programs have contributed to NO_x and SO₂ emissions reductions, as is detailed in this SIP revision.

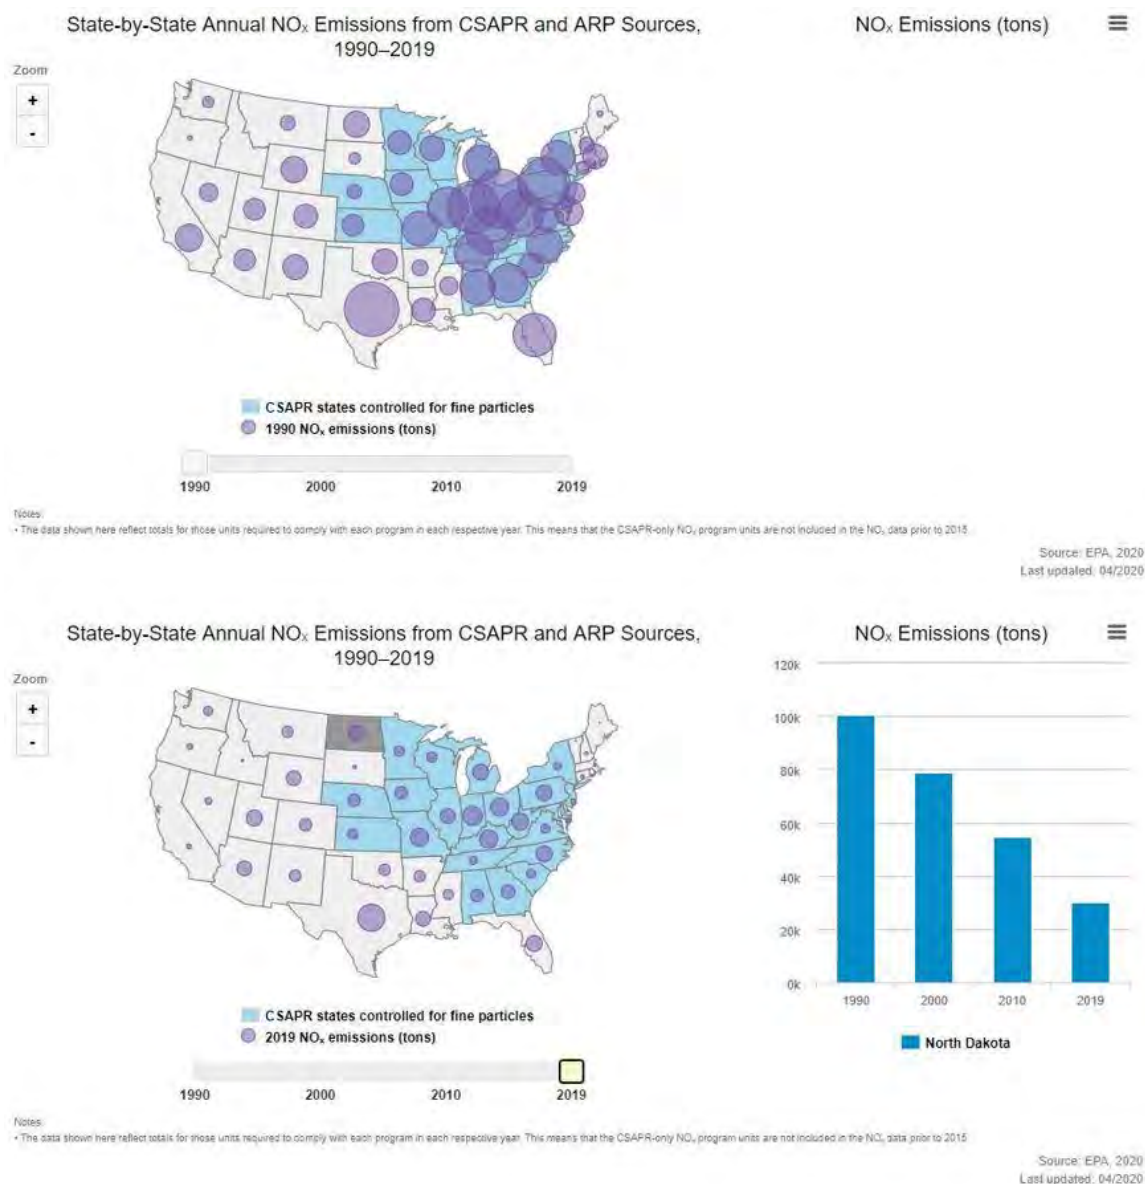

Figure 45: Annual NO_x reductions across the continental United States from 1990–2019. The size of the circle over each state represents a relative scale of emissions. NO_x emissions from North Dakota sources from 1990–2019 is also shown.

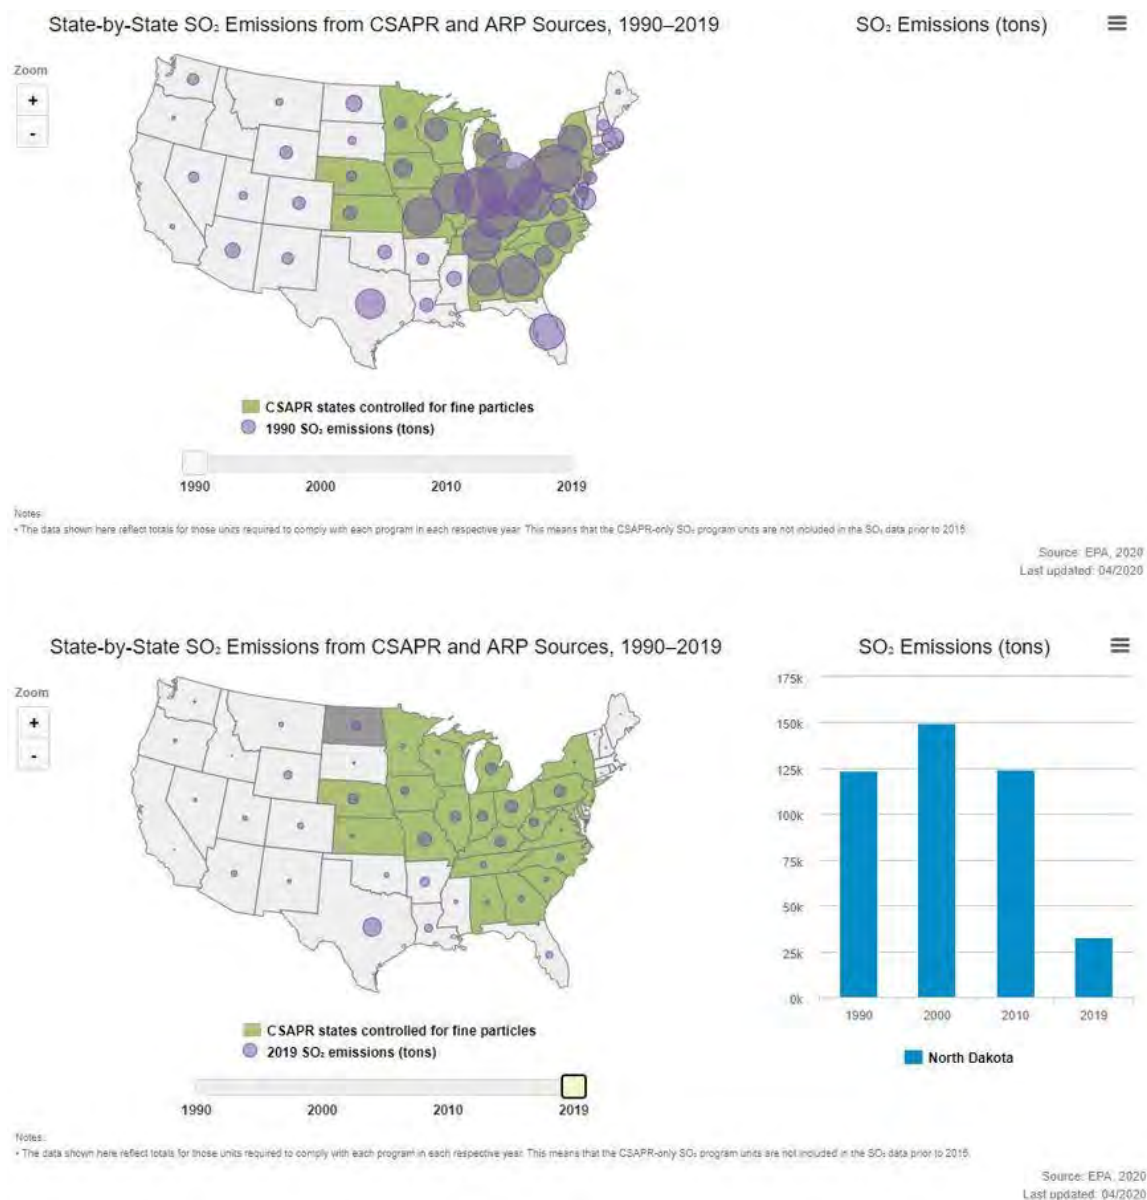

Figure 46: SO₂ reductions across the continental United States from 1990–2019. The size of the circle over each state represents a relative scale of emissions. SO₂ emissions from North Dakota sources from 1990–2019 is also shown.

5.3.1.2.4 Tier 3 Motor Vehicle Emission and Fuel Standards

Tier 3 vehicle standards were established in 2014.¹⁶³ The action established more stringent vehicle emissions standards and reduced the sulfur content of gasoline beginning in 2017. Under the Tier 3 program, federal gasoline cannot contain more than 10 ppm of sulfur on an annual average basis after January 1, 2017. The vehicle standards reduced both tailpipe and evaporative emissions from passenger cars, light-duty trucks, medium-duty passenger vehicles, and some heavy-duty vehicles. The tailpipe

¹⁶³ Available at: <https://www.epa.gov/regulations-emissions-vehicles-and-engines/final-rule-control-air-pollution-motor-vehicles-tier-3> (Last visited December 28, 2020)

standards include different phase-in schedules ranging between model years 2017 and 2025, depending on vehicle class. It is expected that the Tier 3 vehicle standards will result in a 60–80% reduction of NO_x, VOC, CO, PM_{2.5}, and air toxics throughout the country. As such, North Dakota’s CIAs will experience less visibility impairment when newer vehicles are operating within or near the CIAs. 2028 emissions projections from non-road and on-road engines were generated using the Motor Vehicle Emission Simulator (MOVES) look-up tables generated by EPA, starting from the 2016v1 platform.¹⁶⁴ See Sections 4.4 and 4.5 for the current emissions from these sectors and projected emissions for 2028.

5.3.1.2.5 Tier 4 Emission Standards for Nonroad Diesel Engines

The EPA finalized Tier 4 emission standards for nonroad diesel engines and sulfur reductions in nonroad diesel fuel in 2004. The new emission standards took effect for new engines beginning in 2008 and were fully phased in by the end of 2015. The rule set standards reducing NO_x and PM emissions by more than 90 percent from nonroad diesel equipment and reduced sulfur emissions from nonroad diesel fuel by more than 99 percent. A reduction on NO_x, PM, and sulfur emissions from nonroad diesel engines benefits visibility across the United States.

5.3.1.2.6 Emission Standards for New Nonroad Engines

The EPA adopted new standards for NO_x, CO, and hydrocarbons emissions from previously unregulated nonroad large industrial spark-ignition engines and recreational vehicles in 2002. The new standards also include requirements for diesel marine engines. The rule was fully phased in by 2012. It is estimated that the rule resulted in a 72 percent reduction in hydrocarbon emissions, an 80 percent reduction in NO_x emissions, and a 56 percent reduction in CO emissions. These reductions benefit visibility across the United States.

5.3.1.2.7 Heavy Duty Highway Engine and Vehicle Standards

The EPA set a PM emissions standard for new heavy-duty engines of 0.01 grams per brake-horsepower-hour (g/bhp-hr), to take full effect for diesel engines in the 2007 model year. The rule also includes standards for NO_x and non-methane hydrocarbons (NMHC) of 0.20 g/bhp-hr and 0.14 g/bhp-hr, respectively. These NO_x and NMHC standards were phased in together between 2007 and 2010 for diesel engines.¹⁶⁵ Sulfur in diesel fuel was lowered to enable modern pollution control technology to be effective on trucks and buses. The EPA required a 97 percent reduction in the sulfur content of highway diesel fuel from its previous level of 500 parts per million (low sulfur diesel) to 15 parts per million (ultra-low sulfur diesel).¹⁶⁶

The EPA announced plans for the Cleaner Trucks Initiative (CTI) on November 13, 2018. The purpose of the CTI is to update standards for NO_x emissions from highway heavy-duty vehicles and engines. An advanced notice of proposed rulemaking was posted to the Federal Register on January 21, 2020

¹⁶⁴ Available at:

https://views.cira.colostate.edu/docs/wrap/mseipp/WRAP_MSEI_Summary_Memo_13Mar2020.pdf. (Last visited December 28, 2020)

¹⁶⁵ Available at: <https://www.federalregister.gov/d/01-2/p-284>. (Last visited December 28, 2020)

¹⁶⁶ Available at: <https://www.federalregister.gov/d/01-2/p-279>. (Last visited December 28, 2020)

requesting comments on the CTI.¹⁶⁷ Comments on the proposed rule were due by February 20, 2020. No further updates have been released, but a reduction in NO_x emissions from highway heavy-duty vehicles and engines would improve visibility across the United States.

5.3.1.2.8 Finding of Significant Contribution and Rulemaking for Certain States in the Ozone Transport Assessment Group Region for Purposes of Reducing Regional Transport of Ozone (NO_x SIP Call)

The EPA finalized the NO_x SIP Call in October 1998. Since NO_x is a major precursor to ozone, the NO_x SIP Call focuses on NO_x reductions. The NO_x SIP Call was designed to mitigate significant transport on NO_x. Phase I of the NO_x SIP Call applies to EGUs and large non-EGUs, including industrial boilers and turbines, and cement kilns in the eastern United States. The NO_x SIP Call is expected to reduce NO_x emissions by 90%. When winds are from the easterly direction, North Dakota CIAs will likely experience an improvement in visibility.

5.3.1.2.9 National Emission Standards for Industrial, Commercial, and Institutional Boilers and Process Heaters (40 CFR 63, Subpart DDDDD)

The EPA issued final rules to substantially reduce emissions of toxic air pollutants from industrial, commercial, and institutional boilers and process heaters (40 CFR 63, Subpart DDDDD) in 2004. The rule reduced emissions of several toxic air pollutants including hydrogen chloride, manganese, lead, arsenic, and mercury. Regulations within the rule also reduced emissions of SO₂ and PM. The rule has been updated several times, with the most recent update being finalized in 2015. The District of Columbia Circuit remanded several of the emission standards to the EPA in 2016 and 2018. The EPA proposed amendments to the rule in 2020 to update the issues identified when the rule was remanded.

5.3.1.2.10 National Emission Standards for Hazardous Air Pollutants: Coal- and Oil-Fired Electric Utility Steam Generating Units (40 CFR 63, Subpart UUUUU)

The EPA issued final rules to substantially reduce emissions of toxic air pollutants from coal- and oil-fired EGUs in 2012, known as the Mercury and Air Toxics Standards (MATS). The MATS reduces emissions of HAPs, including mercury, from the electric power industry. As a co-benefit, the emissions of certain PM_{2.5} precursors such as SO₂ also declined.¹⁶⁸ The rule has been updated several times, with the most recent update being finalized in 2020.¹⁶⁹

5.3.1.2.11 Various Other Maximum Achievable Control Technology (MACT) Standards

Various MACT standards have been promulgated by the EPA that will limit or reduce various visibility impairing pollutants, including PM, NO_x, SO₂, and VOC which were not discussed above. Table 37 provides a listing of MACT standards for source categories where controls are to be installed after 2002. This list does not include items covered above (i.e. MACT DDDDD and MACT UUUUU).

5.3.2 §51.308(f)(2)(iv)(B) – Measures to Mitigate the Impacts of Construction Activities

As part of the long-term strategy requirements, 40 CFR 51.308(f)(2)(iv)(B) requires the consideration of measures to mitigate the impacts of construction activities. North Dakota regulates fugitive emissions by rule using NDAC Chapter 33.1-15-17. Section 33.1-15-17-01(2) states:

“No person shall cause or permit fugitive emissions from any source whatsoever, including a building, its appurtenances, or a road, to be used, constructed, altered, repaired, or demolished; or activities such as loading, unloading, storing, handling, or transporting of materials without taking reasonable precautions to prevent such emissions from causing air pollution as defined in section 33.1-15-01-04.”

NDAC Section 33.1-15-17-02 also states, in part:

“No person shall emit or cause to be emitted into the ambient air from any source of fugitive emissions as specified in section 33.1-15-17-01 any particulate matter which:

- 2. Exceed the ambient air quality standards of chapter 33.1-15-02 at or beyond the property line of the source.*
- 3. Exceed the prevention of significant deterioration of air quality increments of chapter 33.1-15-15 at or beyond the property line of the source for sources subject to chapter 33.1-15-15.*
- 4. Exceed the restrictions on the emission of visible air contaminants of chapter 33.1-15-03, at or beyond the property line of the source, except as provided in section 33.1-15-03-04.*

5. *Would have an adverse impact on visibility, as defined in chapter 33.1-15-19, on any class 1 federal area.”*

The Department requires permits for asphalt concrete plants in addition to rock, sand and gravel plants, which are generally associated with major construction projects. The Department requires notification of the relocation of asphalt plants in order to track any emissions from these facilities.

The CIAs in North Dakota are located in the western and northwestern portion of the State. The largest population centers in North Dakota are Fargo and West Fargo (combined population of ~160,000), Bismarck (population of ~80,000), and Grand Forks (population of ~60,000). Of North Dakota’s largest population centers, Bismarck is the closest to North Dakota’s CIAs and is just over 200 km from the south unit of Theodore Roosevelt National Park. Watford City is the closest population center to any of North Dakota’s CIAs. Watford City has a population of ~8,000 and is ~40 km from the north unit of Theodore Roosevelt National Park.

Most potential impacts on visibility in North Dakota CIAs due to construction activities would likely be associated with road development, oil and gas well pads, compressor stations, and gas processing plants. Combustion emissions of NO_x and SO₂ (and other common visibility impairing pollutants) from the operation of the non-road engines used to support construction activity are included in Section 4.4. There is also a potential for dust formation during construction of these source types due to the arid conditions of North Dakota. Owners of sources subject to permitting requirements, including facilities such as compressor stations and gas processing plants, are subjected to fugitive dust control requirements included in the permit issued for the construction of the facility. These emissions are generally ground level emissions and dissipate quickly. Therefore, the emissions do not typically travel very far. All sources, included those not permitted, are subject to the requirements of NDAC Chapter 33.1-15-17. In addition, NDAC Section 33.1-15-17-03 lists measures considered to be reasonable precautions for abating and preventing fugitive dust. These include:

- “1. Unpaved roads and unpaved parking areas. Abatement and preventive measures include frequent watering, addition of dust palliatives, detouring, paving, closure, speed control, or other means such as surface treatment with penetration chemicals (ligninsulfonates, oil, water, cutbacks, etc.) or methods of equal or greater effectiveness in reducing the air contamination produced.*
- 2. Demolition, wrecking and explosive detonation activities, earth and construction material moving, mining, and excavation activities.*
 - a. Abatement and preventive fugitive particulate control measures include:*
 - (1) Wetting down, including prewatering.*
 - (2) Landscaping and replanting with native vegetation.*
 - (3) Covering, shielding, or enclosing the area.*
 - (4) Paving, temporary or permanent.*
 - (5) Treating, the use of dust palliatives and chemical stabilization.*
 - (6) Detouring.*
 - (7) Restricting the speed of vehicles on sites.*
 - (8) Preventing the deposit of dirt and mud on improved streets and roads.*
 - (9) Minimizing topsoil disturbance and reclaiming as soon as possible.*

- b. *Sequential blasting be employed whenever or wherever feasible to reduce the amounts of particulate matter.*
- c. *Such dust control strategies as revegetation, delay of topsoil disturbance until necessary, or surface compaction and sealing, be applied.*
- d. *Haulage equipment be washed or wetted down, treated, or covered when necessary to minimize the amount of dust becoming airborne in transit and in loading.*
- e. *Stockpile of materials be treated to prevent blowing or the material be contained in silos or other suitable enclosures.*
- f. *Waste disposal sites be so operated and constructed as to prevent particulate matter from becoming airborne.*
- g. *All conveyors, transfer points, crushers, screens, and dryers be so constructed, protected, or treated as to prevent particulate matter from becoming airborne.*
- h. *These measures also be used during period when actual construction work is not being conducted, such as on weekends and holidays.”*

5.3.3 §51.308(f)(2)(iv)(C) – Source Retirement and Replacement Schedules

As part of the long-term strategy requirements, 40 CFR 51.308(f)(2)(iv)(C) requires that each state consider any source retirement and replacement schedules in developing its long-term strategy.

Great River Energy’s 160 MWe Stanton Station was shut down on May 1, 2017. Unit 1 had a nominal heat input capacity of 1,800 MMBtu/hr and Unit 10 had a nominal heat input capacity of 642 MMBtu/hr. As documented in Table 35, the average annual combined SO₂ and NO_x emissions from 2012 through 2016 were 3,218 tons for Unit 1 and 701 tons for Unit 10. Stanton Station’s Unit 1 had a Q/d of 21 and Unit 10 had a Q/d of 4. These pollutants are no longer being emitted into the atmosphere and visibility in North Dakota’s CIAs could improve as a result. On October 11, 2018, Stanton Station was demolished in a planned implosion¹⁷⁰ and restoration of the site has since been completed¹⁷¹.

In February of 2019, Montana Dakota Utilities Company announced that the 100 MWe R.M. Heskett Station will be replaced by a natural gas-fired combustion turbine in 2023. Unit 1 has a nominal heat input capacity of 388 MMBtu/hr and Unit 2 has a nominal heat input capacity of 917 MMBtu/hr. As documented in Table 35, the average annual combined SO₂ and NO_x emissions from 2012 through 2016 were 1,269 tons for Unit 1 and 2,941 tons for Unit 2. The R.M. Heskett Station’s Unit 1 has a Q/d of 7 and Unit 2 has a Q/d of 16. The switch will result in a significant reduction in visibility impairing emissions. Unit 1 and Unit 2 shutdown in January and February of 2022.¹⁷²

In May of 2020, Great River Energy announced that the 99 MWe Spiritwood Station will be modified to be fueled by only natural gas.¹⁷³ Unit 1 has a nominal heat input capacity of 1,280 MMBtu/hr and can be currently fired with coal, natural gas, or propane. As documented in Table 35, the average annual

¹⁷⁰ Video Available at: https://www.youtube.com/watch?v=ebLV5_81E0k (Last visited August 9, 2021)

¹⁷¹ Available at: <https://greatriverenergy.com/stanton-station-demolition-restoration-complete/> (Last visited August 9, 2021)

¹⁷² See Appendix A.6.

¹⁷³ Available at: <https://greatriverenergy.com/major-power-supply-changes-to-reduce-costs-to-member-owner-cooperatives/> (Last visited December 29, 2020)

combined SO₂ and NO_x emissions from 2012 through 2016 were 142. Unit 1 has a Q/d of 0. Although the reduction in emissions resulting from the transition to only natural gas-fired combustion is not yet known, the switch will result in a reduction in emissions and potential visibility improvement across North Dakota.

The 2028 modeling conducted by WRAP included the retirement of Great River Energy's Stanton Station and R.M Heskett Station coal units but did not include the future fuel switch at Spiritwood Station. Emissions are displayed in Section 4 and the modeling results are covered in Section 6.

5.3.4 §51.308(f)(2)(iv)(D) – Basic Smoke Management Practices

As part of the long-term strategy requirements, 40 CFR 51.308(f)(2)(iv)(D) requires that each state consider basic smoke management practices for prescribed fire used for agricultural and wildland vegetation management purposes and smoke management programs. North Dakota has a land area of approximately 69,000 square miles (44 million acres). Of this total, 28 million acres is crop land, 10 million acres is pastureland and 203,000 acres is woodland.¹⁷⁴ The five State forests of North Dakota comprise a total of 13,613 acres. The North Dakota State Implementation Plan contains rules which govern prescribed burning on crop land, pasture/rangeland and woodland. NDAC Section 33.1-15-04-02(2) lists the conditions that apply to any prescribed burning, which include:

- a. Air pollution, as defined in section 33.1-15-1-04, will not be created.*
- c. Care must be used to minimize the amount of dirt on the material being burned and the material must be dry enough to burn cleanly.*
- d. Oils, rubber, and other materials that produce unreasonable amounts of air contaminants may not be burned.*
- e. The burning may be conducted only when meteorological conditions favor smoke dispersion and air mixing.*
- h. Except in an emergency, burning may not be conducted in such proximity of any Class I area, as defined in chapter 33.1-15-15, that the ambient air of such area is adversely impacted.*
- i. Except in an emergency, the visibility of any Class I area cannot be adversely impacted as defined in chapter 33.1-15-19.*
- j. Burning activities must be attended and supervised at all times burning is in progress.*
- k. If state or local fire officials determine conditions to be unsafe for open burning, such burning must cease until conditions are deemed safe by such officials."*

In addition, NDAC Section 33.1-15-04-02(1)(e) requires that "*Fires purposely set to forest or rangelands for a specific reason in the management of forest, rangeland, or game in accordance with practices recommended by state or federal agencies, as appropriate...*" be "*...approved in advance by the department*". Although agricultural crop burning does not require advanced approval by the Department, most of this burning occurs in the eastern two thirds of North Dakota. North Dakota's CIAs are in the western and northwestern portions of the state. WRAP has estimated the 2014 annual emissions from

¹⁷⁴ 2017 Census of Agriculture State Profile for North Dakota Available at: https://www.nass.usda.gov/Publications/AgCensus/2017/Online_Resources/County_Profiles/North_Dakota/cp99038.pdf. (Last visited December 29, 2020)

fire in North Dakota as shown in Table 38. Fire emissions estimations for each of the emissions inventories are included in Section 4.1. For comparison to other western states, wildfire activity emissions from all the WRAP states are included in Section 4.8.

Table 38: 2014 emissions from fire in North Dakota (tons)

Source	Sector	NO _x	SO ₂	PM ₁₀	PM _{2.5}
Anthropogenic	ag_flaming	1,187	402	5,252	3,457
Anthropogenic	rxfire	301	225	3,812	3,231
Natural	wildfire	32	17	288	242
Total		1,520	644	9,352	6,930

5.3.5 §51.308(f)(2)(iv)(E) – Anticipated Net Impact on Visibility due to Projected Emissions Changes over the Long-term Strategy Period

As part of the long-term strategy requirements, 40 CFR 51.308(f)(2)(iv)(E) requires that each state consider the anticipated net effect on visibility due to projected changes in point, area, and mobile source emissions over the period addressed by the long-term strategy. The anticipated net change in visibility due to projected changes in emissions through 2028 is discussed in Section 6.1, and the visibility projections are covered in Sections 3.1 and 6.1.1.

6 §51.308(f)(3) – Modeling of Long-Term Strategy to Set Reasonable Progress Goals

40 CFR §51.308(f)(3)(i) of the RHR requires the Department to establish a reasonable progress goal (RPG) for each CIA located within North Dakota, expressed in deciviews, that reflects the visibility conditions that are projected to be achieved by the end of the implementation period resulting from the long-term strategy (LTS). The LTS contains the measures adopted upon consideration of the four factors required under 40 CFR §51.308(f)(2) (Section 5.2), control measures that other contributing states have determined to be necessary to make reasonable progress (Section 2.3), and state or federal measures adopted to meet other requirements of the CAA (Section 5.3) to determine the necessary RPG for the implementation period.

The Department evaluated projected future visibility conditions using photochemical grid modeling (PGM) completed by WRAP, Section 3.1 and Appendix C. The modeling protocols and framework were developed by the WRAP Regional Technical Operations Work Group and are consistent with the US EPA RHR Guidance.¹⁷⁵

6.1 Establishment of RPGs

The LTS and RPGs for CIAs must provide for improvement of visibility for the MIDs since the baseline period and ensure no degradation of visibility for the clearest days since the baseline period.¹⁷⁶ As stated in the July 1, 1999 final regional haze rule: *“EPA was mindful of the balance that must be maintained between the need for strategies that will achieve meaningful improvements in air quality and the need to provide appropriate flexibility for States in designing strategies that are responsive to both air quality and economic concerns.”*¹⁷⁷ The two factors, *“meaningful improvement in air quality”* and *“economic concerns”* are very important during this planning period. The Department has significant economic and energy security concerns regarding the sources and industries evaluated. The Department addresses the meaningful improvement in air quality (visibility) in this Section by evaluating the projected impact additional controls have on overall visibility. Additionally, North Dakota remains in compliance with all national ambient air quality standards. Therefore, any potential emissions reduction measures recommended for regional haze will not have the added benefit of helping North Dakota achieve compliance with ambient air quality standards.

Also, as stated in the July 1, 1999 final rule: *“the CAA national visibility goal and “reasonable progress” provisions do not mandate specific rates of progress, but instead call for “reasonable progress” toward the ultimate goal of returning to natural background conditions”*.¹⁷⁸ In other words, a RPG is a projected outcome, rather than visibility conditions established directly, and meeting an RPG is not an enforceable requirement of the RHR. RPGs are still, however, a useful metric for evaluating progress. The Department believes the current rate of visibility improvement projected by the end of the planning period is

¹⁷⁵ Available at: <https://www.epa.gov/visibility/visibility-guidance-documents> (Last visited January 27, 2021)

¹⁷⁶ 40 CFR 51.308(f)(3)

¹⁷⁷ 64 FR 35731

¹⁷⁸ 64 FR 35731

reasonable for making progress toward the 2064 visibility goal, supported by the Department's visibility analysis in Section 3. Therefore, the Department is not requiring additional progress beyond what is already expected to occur during this planning period. The Department came to this conclusion in consideration of the four factors and through the WRAP PGM modeling of current and potential additional controls. The modeling results provided in Section 6.1.1 help to further support this position.

When establishing the RPGs, the Department considered the four statutory factors for the affected sources (Section 5.2). The Department also analyzed and determined the rate of progress needed to attain natural visibility conditions by the year 2064. To calculate this rate of progress, the Department compared baseline visibility conditions to natural visibility conditions in the CIAs and determined the uniform rate of visibility improvement (measured in deciviews) that would need to be maintained in order to attain natural visibility conditions by 2064 (Section 3.2.6 and Section 3.2.7). In establishing the RPGs, the Department considered the uniform rate of visibility improvement and any emission reduction measures needed for the period covered by the implementation plan. It was determined that no additional emissions reductions measures were appropriate or necessary to achieve the RPGs for this planning period. The PGM results for LWA and TRNP show that each CIA is projected to provide for an improvement in visibility for the MIDs and no degradation of visibility for the clearest days over the implementation plan. The 2028 visibility projections for the MIDs and clearest days can be found in Section 3.1.

6.1.1 Modeling of Potential Additional Controls

The Department projected the future 2028 baseline visibility conditions assuming no changes to the current emissions controls on the stationary sources in North Dakota.¹⁷⁹ The Department then selected potential additional controls (PAC) at two stationary sources for the 2028 visibility modeling evaluation. Each of these sources was subject to the reasonable progress requirement from the first-round planning period. Two scenarios of controls were reviewed to determine the PACs impact on the visibility projections for 2028 (i.e. how much improvement over the 2028 baseline is expected with these controls). Modeling with two different scenarios also helps show how sensitive the model is to the potential reductions being evaluated. These two scenarios, along with the 2028 OTB scenario (or 2028 baseline), give the Department three future data points. 1) What is the current projected visibility for 2028 with no additional changes outside of what is expected? 2) What impact to the projected 2028 visibility conditions do the potential additional control have, for each PAC1 and PAC2? 3) With the three points (2028OTB, 2028PAC1, and 2028PAC2), how sensitive is the model to the magnitude of reductions evaluated and will this meaningfully impact future visibility conditions on the MID?

All the sources evaluated in Section 5.2 were considered for additional controls during this planning period. Two sources were identified as candidates for potential additional controls. The candidates evaluated for additional reasonable controls were the Coyote Station coal fired EGU and the Antelope Valley Station coal fired EGU. The emission reductions expected with the controls evaluated are addressed

¹⁷⁹ Section 4.2.1.1.1 discusses Coal Creek Station's expected SO₂ reductions prior to 2028. These are no longer being considered as a result of the pending ownership change to Rainbow Energy Center.

in Section 4.1.7. The controls selected for modeling review and supporting rational is addressed in Section 5.2.1 for Coyote Station and 5.2.2 for Antelope Valley Station.

Figure 47 and Figure 48 display the 2028OTB (2028 baseline), 2028PAC1, and 2028PAC2 projected visibility conditions for LWA and TRNP, respectively.

The recommended procedure to project 2028 visibility with and without added controls is the EPA default visibility projection procedure without fire impacts (EPA w/o fire). The other options available are the EPA recommended default (EPA default) visibility projection procedure and the modeled MIDs procedure. As described throughout this SIP revision, North Dakota experiences significant adverse impacts that result from wildfires outside of North Dakota. However, North Dakota is not heavily impacted by fire events on the IMPROVE MIDs. Therefore, as expected, the difference between the EPA default procedure and the EPA w/o fire procedure is small. The 2028 visibility projection using the EPA default is 0.02 deciviews greater than the 2028 projection using the EPA default w/o fire, meaning the modeled fire contribution on the MIDs was 0.02 deciviews. The 0.02 deciviews is for TRNP and LWA. The modeled MIDs procedure produced 2028 visibility impairment projections lower than the EPA w/o fire (also lower than EPA default). The modeled MIDs procedure uses the results from the source apportionment modeling to select the MIDs. The first two options use the IMPROVE observed (or monitored) MIDs. In addition to the EPA w/o fire procedure being the WRAP RTO recommendation, this procedure yielded the second most conservative (less projected improvement) results and the difference between EPA default and EPA default w/o fire is insignificant.

As outlined in Section 3.2.7, the recommended procedure to adjust the glidepath endpoint was the procedure accounting for international emissions and prescribed wildland fires. Also as noted in Section 3.2.7, a significant majority of the adjustment is due to international sources, not from wildland prescribed fires. Similar to the difference in 2028 visibility projections between the EPA default and the EPA default w/o fire, the impact from prescribed wildland fires is minimal to the glidepath endpoint. Prescribed wildland fires account for 0.13 deciviews of the overall 6.72 deciview adjustment at LWA. Prescribed wildland fires account for 0.09 deciviews of the overall 5.61 deciview adjustment at TRNP. Representing less than two percent of the overall adjustment.

For complete details of these procedures, see the white paper produced by the WRAP RTO group at: https://www.wrapair2.org/pdf/2028_Vis_Proj_Glidepath_Adj_2021-03-01draft_final.pdf.

For visual aesthetics, Figure 47 and Figure 48 only show the 2028 visibility projections and glidepath adjustment produced using the recommended procedures by the WRAP RTO.¹⁸⁰

Figure 47 and Figure 48 each display multiple important elements. The five-year rolling average IMPROVE monitor network data shows the progress made to date. The unadjusted glidepath and the adjusted glidepath demonstrate the impact international emissions and prescribed wildland fires have on hampering North Dakota's ability to achieve the end goal without an adjusted glidepath. There are three

¹⁸⁰ Available at: https://www.wrapair2.org/pdf/2028_Vis_Proj_Glidepath_Adj_2021-03-01draft_final.pdf (Last visited March 17, 2021)

projected visibility outcomes based on projected 2028 emissions scenarios, which can be summarized as a baseline 2028 projection “2028OTB”, a projection with strict emissions controls on selected units “2028PAC1”, and a projection lower cost control options “2028PAC2”.

Figure 47: LWA Visibility Projection for the Most Impaired Days with 2028 Emissions Scenarios

The 2028OTB projection in Figure 47 shows a modeled cumulative visibility impairment of 15.78 deciviews. The emissions data which produced this projection can be found in Section 4.1.6. Comparing the 2028OTB projection against the adjusted glidepath indicates that LWA is anticipated to remain below the adjusted glidepath through 2028. The adjusted glidepath slope indicates LWA needs to be below 16.0 deciviews to remain below the adjusted uniform rate of progress. If no additional reduction measures beyond what is already planned are implemented during this planning period, LWA can reasonably expect to have a visibility impairment of 15.78 deciviews in 2028. The 2028OTB projection of 15.78 deciview impairment is lower than the most recent 16.18 deciview impairment resulting from the five-year IMPROVE monitor network average from 2014–2018. Overall, this demonstrates LWA is projected to provide for an improvement in visibility for the MIDs over the period of the implementation plan, meeting the requirements of 40 CFR 51.308(d)(1) and 40 CFR 51.308(f)(3)(i).

Figure 47 also displays the impact to visibility from the additional controls selected for modeling evaluation resulting from consideration of the four factors summarized in Section 5.2. The emissions data and controls selected for review which produced this projection can be found in Section 4.1.7.

The 2028PAC1 projection in Figure 47 shows a modeled cumulative visibility impairment of 15.68 deciviews. Comparing the 2028PAC1 projection against the 2028OTB projection indicates that LWA would

be anticipated to experience a cumulative improvement in visibility of 0.1 deciview resulting from the installation of the controls evaluated under this scenario. *For context, one deciview of change in visibility is generally considered to be the minimum change that the average person can detect with the naked eye.* This 0.1 deciview improvement was derived from the reduction of over 22,200 tons of combined NO_x plus SO₂ emissions. The 0.1 deciview improvement and over 22,000 tons of reductions come at a combined capital cost of approximately \$150 million and a combined annualized cost of approximately \$30 million. Individual unit controls and cost details are covered in Sections 5.2.1, 5.2.2, and 4.1.7. In summary, if North Dakota were to require the 2028PAC1 (emissions reductions) it would come at a very significant cost while not reducing anthropogenic visibility impairment, as defined in §51.301, on the MIDs visibility projection for 2028.

The 2028PAC2 projection in Figure 47 shows a modeled cumulative visibility impairment of 15.74 deciviews. Comparing the 2028PAC2 projection against the 2028OTB projection indicates that LWA would be anticipated to experience a cumulative improvement in visibility of 0.04 deciview resulting from the installation of the controls evaluated under this scenario. This 0.04 deciview improvement was derived from the reduction of over 7,000 tons of combined NO_x plus SO₂ emissions. The 0.04 deciview improvement and over 7,000 tons of reductions come at a capital cost of approximately \$0.5 million and an annualized cost of approximately \$2 million. Individual unit controls and cost details are covered in Sections 5.2.1 and 4.1.7. In summary, if North Dakota were to require the 2028PAC2 (emissions reductions) there would be no reduction in anthropogenic visibility impairment, as defined in §51.301, on the MIDs visibility projection for 2028. Although the cost for this scenario is considerably lower than 2028PAC1, there is also no projected improvement in anthropogenic visibility impairment resulting from the controls, a key factor in the Department's analysis.

LWA is currently projected to meet its 2028 RPGs and is on track to accomplish the 2064 visibility goals. With the modeled control scenarios providing no projected improvement in anthropogenic visibility conditions, the Department determined that it is not reasonable to require additional controls during this planning period. The Department will continue to monitor LWA's visibility progression and will provide an update in the 2025 progress report.

Figure 48: TRNP Visibility Projection for the Most Impaired Days with 2028 Emissions Scenarios

The 2028OTB projection in Figure 48 shows a modeled cumulative visibility impairment of 13.56 deciviews. The emissions data which produced this projection can be found in Section 4.1.6. Comparing the 2028OTB projection against the adjusted glidepath indicates that TRNP is anticipated to remain below the adjusted glidepath through 2028. The adjusted glidepath slope indicates TRNP needs to be below 14.43 deciviews to remain below the adjusted uniform rate of progress. If no additional reduction measures beyond what is already planned are implemented during this planning period, TRNP can reasonably expect to have a visibility impairment of 13.56 deciviews. The 2028OTB projection of 13.56 deciview impairment is lower than the most recent 14.06 deciview impairment resulting from the five-year IMPROVE monitor network average from 2014–2018. Overall, this demonstrates TRNP is projected to provide for an improvement in visibility for the MIDs over the period of the implementation plan, meeting the requirements of 40 CFR 51.308(d)(1) and 40 CFR 51.308(f)(3)(i).

Figure 48 also displays the impact to visibility from the additional controls selected for modeling evaluation resulting from consideration of the four factors summarized in Section 5.2. The emissions data and controls selected for review which produced this projection can be found in Section 4.1.7.

The 2028PAC1 projection in Figure 48 shows a modeled cumulative visibility impairment of 13.48 deciviews. Comparing the 2028PAC1 projection against the 2028OTB projection indicates that TRNP would be anticipated to experience a cumulative improvement in visibility of 0.08 deciview resulting from the installation of the controls evaluated under this scenario. This 0.08 deciview improvement was derived from the reduction of over 22,200 tons of combined NO_x plus SO₂ emissions. The 0.08 deciview

improvement and over 22,000 tons of reductions come at a combined capital cost of approximately \$150 million and a combined annualized cost of approximately \$30 million. Individual unit controls and cost details are covered in Sections 5.2.1, 5.2.2, and 4.1.7. In summary, if North Dakota were to require the 2028PAC1 (emissions reductions) it would come at a very significant cost while not reducing anthropogenic visibility impairment, as defined in §51.301, on the MIDs visibility projection for 2028.

The 2028PAC2 projection in Figure 48 shows a modeled cumulative visibility impairment of 13.53 deciviews. Comparing the 2028PAC2 projection against the 2028OTB projection indicates that TRNP would be anticipated to experience a cumulative improvement in visibility of 0.03 deciview resulting from the installation of the controls evaluated under this scenario. This 0.03 deciview improvement was derived from the reduction of over 7,000 tons of combined NO_x plus SO₂ emissions. The 0.03 deciview improvement and over 7,000 tons of reductions come at a combined capital cost of approximately \$0.5 million and an annualized cost of approximately \$2 million. Individual unit controls and cost details are covered in Sections 5.2.1 and 4.1.7. In summary, if North Dakota were to require the 2028PAC2 (emissions reductions) there would be no reduction in anthropogenic visibility impairment, as defined in §51.301, on the MIDs visibility projection for 2028. Although the cost for this scenario is considerably lower than 2028PAC1, there is also no projected improvement in anthropogenic visibility impairment resulting from the controls, a key factor in the Department's analysis.

TRNP is currently projected to meet its 2028 RPGs and is on track to accomplish the 2064 visibility goals. With the modeled control scenarios providing no projected improvement in anthropogenic visibility conditions, the Department determined that it is not reasonable to require additional controls during this planning period. The Department will continue to monitor TRNP's visibility progression and will provide an update in the 2025 progress report.

6.2 §51.308(f)(3)(ii)(A) – Reasonable Progress Goals Above the Uniform Rate of Progress

Without the adjustment of the uniform rate of progress to account for international and wildland prescribed fire impacts, it would be impossible for North Dakota to reduce anthropogenic emissions enough to meet the uniform rate of progress needed to show the State is making reasonable progress to improve visibility, see Section 3.2.6. Once the uniform rate of progress is adjusted, both TRNP and LWA are below the glidepath. Meaning they are tracking to meet the 2064 natural visibility end goals, see Section 3.2.7 and Section 6.1.1. Overall, the current visibility impairment and the 2028 visibility impairment projections are on track to reach the 2064 natural visibility goals for the MIDs and the least impaired (or clearest) days at both North Dakota CIAs.

6.3 §51.308(f)(3)(ii)(B) – Upwind (out-of-state) Impact on Reasonable Progress Goals

Section 2.1 contains the communications and consultations the Department had with FLMs and neighboring states. None of the neighboring states have provided input regarding any North Dakota impacts to visibility in their respective CIAs nor have they requested additional controls on North Dakota sources.

6.4 §51.308(f)(3)(iii) – Enforceability of Reasonable Progress Goals

The RPGs established in Section 6.1.1 are not directly enforceable but should be considered by the EPA when evaluating the adequacy of the measures included in this SIP revision. The Department believes LWA and TRNP are making reasonable progress toward achieving natural conditions by 2064.

6.5 §51.308(f)(3)(iv) – Evaluation of RPG

The PGM modeling for the projected 2028 baseline visibility condition and modeling with potential additional controls associated with significant emissions reductions (2028PAC1) resulted in no meaningful visibility improvement on the MIDs (Section 6.1.1).

6.6 §51.308(f)(4) – Reasonably Attributable Visibility Impairment (RAVI)

The FLMs for TRNP and LWA have not identified any reasonably attributable visibility impairment from North Dakota. The FLMs for the CIAs that North Dakota's emissions impact in other states have not identified any reasonably attributable visibility impairment caused by North Dakota sources. For these reasons, the Department does not have reasonably attributable visibility impairment to address.

6.7 §51.308(f)(5) – Progress Report

51.308(f)(5) requires the State to address the progress made towards the RPGs identified by the State and to submit a report evaluating the progress made. North Dakota submitted its first five-year periodic progress report in January 2015. With this Regional Haze SIP revision North Dakota has completed an update to the progress report, this update can be found in Section 9.

6.8 §51.308(f)(6) – Monitoring Strategy

40 CFR §51.308(f)(6) of the RHR requires the Department to submit with the implementation plan a monitoring strategy for measuring, characterizing, and reporting of regional haze visibility impairment that is representative of all CIAs within the State. Compliance with this requirement may be met through participation in the Interagency Monitoring of Protected Visual Environments network. North Dakota depends on the IMPROVE program to collect and report aerosol monitoring data for long-term reasonable progress tracking as specified in the RHR.

6.8.1 §51.308(f)(6)(i)

Same requirement as §51.308(d)(4)(i). North Dakota does not believe additional monitoring sites or equipment is needed to assess whether RPGs to address regional haze for the CIAs within the state are being achieved.

6.8.2 §51.308(f)(6)(ii)

Same requirement as §51.308(d)(4)(ii). North Dakota does not directly collect, or handle IMPROVE data. North Dakota relies on the IMPROVE program to meet the monitoring requirements and data collection obligations necessary to determine the contribution of emissions from within North Dakota to regional visibility impairment at CIAs in and outside of North Dakota.

6.8.3 §51.308(f)(6)(iii)

Same requirement as §51.308(d)(4)(iii). North Dakota has two CIAs (Section 1.1), therefore, this section is not applicable to North Dakota.

6.8.4 §51.308(f)(6)(iv)

Same requirement as §51.308(d)(4)(iv). North Dakota does not directly collect, or handle IMPROVE data. North Dakota relies on the IMPROVE program to meet the monitoring requirements and data collection obligations necessary to meet the reporting requirements of this section.

6.8.5 §51.308(f)(6)(v)

Similar to requirement under §51.308(d)(4)(v). The emissions inventories used for this regional haze SIP revision are addressed in Section 4. North Dakota commits to update these emissions inventories periodically, as required by the section.

6.8.6 §51.308(f)(6)(vi)

Same requirement as §51.308(d)(4)(vi). The Department has not identified any other elements, including reporting, recordkeeping, or other measures necessary to assess and report on visibility. Since the Department does not participate in the data collection, quality assurance, or give any input regarding the IMPROVE monitor network operation, it is of the utmost importance to ensure the proper quality assurance and control of the data is maintained. Given that this system is now over 20 years old, North Dakota suggests the FLMs and EPA conduct a comprehensive review to determine if system upgrades are necessary to improve the quality of technical data and performance.

7 Overview of WRAP Modeling Scenarios

WRAP conducted significant modeling which was used to evaluate visibility impairment throughout the western United States. This assisted the Department in determining source and sector contributions to visibility impairment and helped establish the RPGs for North Dakota CIAs. Photochemical modeling was also used to evaluate the impact potential emission reductions had on visibility in North Dakota and nearby CIAs. Additionally, weighted emissions potential and area of influence modeling was completed and assisted in determining which regions and point source emissions may contribute to visibility impairment at CIAs on the MIDs. A brief discussion on the modeling scenarios and references to the supporting technical specification can be found in Sections 7.1 through 7.5. WRAP also developed a document titled “WRAP Technical Support System for Regional Haze Planning: Modeling Methods, Results, and References”. This document describes the WRAP emissions and modeling analyses and illustrates how the technical support system products can be applied to support the 2028 visibility progress demonstrations for western U.S. Class I areas. This document has been included in Appendix C.5.

7.1 Western Region Model Performance Evaluation

WRAP developed a webpage dedicated to the model platform description and model performance evaluation (MPE), https://views.cira.colostate.edu/iwdw/docs/WRAP_WAQS_2014v2_MPE.aspx.

This webpage contains the detailed information used in the final base case 2014 (2014v2) CAMx modeling platform and the configuration used in the 2014v2 modeling scenario. This includes discussion on model sensitivities, tendencies, performance results, and summaries.

7.2 Representative Baseline and 2028 On-the-Books

WRAP completed RepBase and 2028OTB CAMx modeling in addition to the 2014v2 modeling. The RepBase and 2028OTB modeling is primarily used to determine the 2028 visibility projection, as described in Section 7.3. The RepBase and 2028OTB modeling results were also used for the particulate matter source apportionment modeling to separate contributions of natural, various fires, US anthropogenic emissions, and international anthropogenic emissions. The international anthropogenic emissions and prescribed wildland fire components of the source apportionment results are also used to adjust the uniform rate of progress glidepath. Complete details on this modeling can be found in the run specification sheet.¹⁸¹ These details include a description, the source apportionment specifications, and the emissions inventories.

7.3 2028 Visibility Projections and Adjusting Glidepaths

Using the information from the RepBase and 2028OTB CAMx modeling, WRAP completed 2028 visibility projections and adjustments to the uniform rate of progress glidepath. The RepBase and 2028OTB modeling results are used to derive model scaling factors known as relative response factors (RRFs). The RRFs are multiplied by the 2014–2018 IMPROVE MIDs to project 2028 visibility conditions. 2028 visibility projections can be compared to the uniform rate of progress glidepath to visually see if a CIA is on track

¹⁸¹ Available at:

https://views.cira.colostate.edu/docs/iwdw/platformdocs/WRAP_2014/EmissionsSpecifications_WRAP_RepBase2_and_2028OTBa2_RegionalHazeModelingScenarios_Sept30_2020.pdf (Last visited May 18, 2021)

to meet its 2064 visibility goals. Also included with this modeling product, is the methodology used to adjust the uniform rate of progress glidepath to account for international anthropogenic emissions and prescribed wildland fires. For North Dakota's CIAs, the 2028 visibility projections, the uniform rates of progress glidepath, and the adjusted uniform rate of progress glidepath are displayed in Sections 3.1 and 6.1.1. Complete details on the procedures followed for making the visibility projections and adjustments to the glidepath can be found in the whitepaper "Procedures for Making Visibility Projections and Adjusting Glidepaths using the WRAP-WAQS 2014 Modeling Platform".¹⁸²

7.4 Regional, State, and Sector Source Apportionment Modeling using the 2028 On-the-Books Emissions Scenario

The RepBase and 2028 OTB CAMx modeling results were further separated to determine the individual contributions from natural sources, fires, and anthropogenic emissions. These include both the US and International sources and is known as the Regional source apportionment or the high-level source apportionment. The results from the 2028OTB regional source apportionment modeling are included in Section 3.1 and Appendix C. Results from the RepBase regional source apportionment modeling can be found on the TSSv2 under the Modeled Data Analysis using source apportionment products 10 through 16.

The 2028 OTB CAMx modeling results were further separated to determine the ammonium nitrate and ammonium sulfate contributions for the 13 consecutive WRAP states for five sector categories. The 5 sectors included in the modeling were: EGU, OilGas (oil and gas point and area sources with tribal oil and gas assigned to the state), NonEGU (all other point), Mobile (mobile on-road, non-road, rail, commercial marine vessels), and RemainAnthro (all remaining anthropogenic emissions including fugitive dust, agricultural, agricultural fire, residential wood combustion, and all other remaining nonpoint sources). These results are known as the State and Sector source apportionment or the low-level source apportionment. The results from the 2028OTB regional source apportionment modeling are included in Section 3.1 and Appendix C.2. Results from the 2028OTB State and Sector source apportionment modeling can also be found on the TSSv2 under the Modeled Data Analysis using source apportionment product 9.

Complete details on this modeling including a description and the source apportionment specifications can be found in the run specification sheet.¹⁸³

7.5 2028 Weighted Emissions Potential (WEP) / Area of Influence (AOI)

Weighted Emissions Potential (WEP) and Area of Influence (AOI) analysis were completed for Regional Haze planning uses in the western U.S. The analysis was performed for the MID during each year of the 5-

¹⁸² Available at: https://www.wrapair2.org/pdf/2028_Vis_Proj_Glidepath_Adj_2021-03-01draft_final.pdf. (Last Visited May 17, 2021)

¹⁸³ Available at: https://views.cira.colostate.edu/docs/iwdw/platformdocs/WRAP_2014/SourceApportionmentSpecifications_WRA_P_RepBase2_and_2028OTBa2_High-LevelPMandO3_and_Low-Level_PM_andOptionalO3_Sept29_2020.pdf. (Last Visited May 19, 2021)

year period from 2014 through 2018 at 76 IMPROVE monitoring sites representing 116 CIAs in the 13 states of the contiguous WESTAR-WRAP region and neighboring states.

These products were used qualitatively to assist the Department in selection of the appropriate source categories that have the highest potential to contribute to visibility impairment from NO_x and SO₂. Potential visibility impairment was evaluated using the 2028OTB emissions inventory for the CIAs in North Dakota and nearby out of state CIAs. The Department's summary analysis can be found in Appendix C.3. A detailed description of this task and access to the complete products is available at: <https://views.cira.colostate.edu/tssv2/WEP-AOI/>.

These products confirmed that the Department's selection of sources for four factor evaluation using the Q/d approach was appropriate.

8 §51.308(e) – Coal Creek Station BART

This section addresses Best Available Retrofit Technology (BART) from Round 1 of the RHR. North Dakota has currently completed all the BART requirements from Regional Haze Round 1 Implementation apart from NO_x BART for Great River Energy's Coal Creek Station Unit 1 and Unit 2.

Coal Creek Station (CCS) is a two-unit, approximately 1,200 gross MW mine-mouth power plant consisting primarily of two steam generators and associated coal and ash handling systems. Unit 1 and Unit 2 are identical Combustion Engineering boilers firing pulverized lignite coal tangentially. Unit 1 has a heat input capacity of 6,015 MMBtu per hr. Unit 2 has a heat input capacity of 6,022 MMBtu per hr. Unit 1 began commercial operation in 1979. Unit 2 began commercial operation in 1980. The facility is located in south central McLean County about five miles south of the town of Underwood, North Dakota and three miles west of US Highway 83. CCS receives lignite coal from the Falkirk Mine that is operated by the Falkirk Mining Company, a subsidiary of the North American Coal Corporation.

The Department emailed Great River Energy on December 18, 2018 to inform Great River Energy that they should focus on completing an updated BART analysis for the first round of Regional Haze planning.¹⁸⁴ On September 12, 2019, Great River Energy submitted an updated BART analysis associated with the first round of Regional Haze planning.¹⁸⁵ Great River Energy announced plans to retire Coal Creek in the second half of 2022 on May 7, 2020.¹⁸⁶ With this retirement announcement, the Department halted work on the updated NO_x BART proposal. On June 30, 2021 the Department learned Great River Energy reached an agreement with Rainbow Energy Center (REC) for the sale of Coal Creek Station.¹⁸⁷ Therefore, the Department continued work on an updated NO_x BART and decided the most reasonable path forward was to include this determination with this SIP revision. This section provides the objective of the NO_x BART determination, a more detailed accounting of the background and history for this facility, and an overview of the BART determination.

Appendix F contains the Department's detailed NO_x BART analysis, the proposed permit to construct incorporating the NO_x BART limits, and additional supporting documentation. This BART determination also serves as the round 2 reasonable progress determination. Appendix B.4.b contains the NO_x BART analysis received by Great River Energy, Coal Creek Station. On August 5, 2021 REC agreed to adopt the NO_x BART analysis submitted by Great River Energy on September 12, 2019.

8.1 BART Objective

The Department's objective with this action is to receive a federally approved SIP imposing BART limits for NO_x emissions from CCS Unit 1 and Unit 2. This updated BART determination for Unit 1 and Unit 2 NO_x emissions at CCS supersedes any previously submitted material. The Department has conducted this new

¹⁸⁴ Appendix B.4.c., PDF page 1082.

¹⁸⁵ Appendix B.4.b., PDF page 576.

¹⁸⁶ Appendix B.4.c., PDF page 1084. Also available at: <https://greatriverenergy.com/major-power-supply-changes-to-reduce-costs-to-member-owner-cooperatives/> (Last visited December 29, 2020)

¹⁸⁷ Available at: <https://greatriverenergy.com/rainbow-energy-center-to-purchase-coal-creek-station/> (Last visited July 6, 2021)

stand-alone BART analysis and BART determination for CCS Unit 1 and Unit 2 NO_x emissions to remove any confusion regarding previously submitted SIP information.

8.2 BART Applicability and History

The BART guidelines apply to CCS Units 1 and 2 because they are part of a fossil-fuel steam electric plant with a total generating capacity in excess of 750 megawatts (MW). Units 1 and 2 are each rated at more than 250 million British thermal units per hour (MMBtu/hr) of heat input. In addition, CCS has the potential to emit more than 250 tons per year (tpy) or more of a visibility-impairing pollutant. This specifically includes SO₂, NO_x, and inhalable particulate matter with a diameter of 10 microns or less (PM₁₀) at CCS. CCS was also determined to have a significant impact on visibility in North Dakota's CIAs (see Section 7.3 of the regional haze SIP submitted in March 2010).

The first proposed regional haze SIP amendment was submitted by North Dakota to EPA Region 8 in March 2010. This SIP amendment was initially deemed complete by the EPA R8 in April 2010. However, during the EPA's review, errors were discovered in the submission, which were specific to the Great River Energy's CCS BART analysis for NO_x emissions. In June 2012, North Dakota received a revised NO_x BART analysis from CCS which addressed the errors raised by the EPA. In January 2013, North Dakota submitted "Supplement No. 2" to EPA which addressed errors in the NO_x BART analysis for CCS. "Supplement No. 2" provided updated and corrected information to the NO_x BART analysis but did not change the original BART determination. In the spring of 2018, the EPA concurred with North Dakota and proceeded with the required public comment period prior to making a final determination on the Department's NO_x BART determination, including the Department's submitted "Supplement No. 2". EPA received comments¹⁸⁸ on North Dakota's proposed BART determination, which were deemed to have merit. The EPA decided not to proceed with final approval of the Department's BART determination until the comments were adequately addressed. Since the EPA's decision to not proceed with a final approval, North Dakota, EPA Region 8, and CCS have been engaged to resolve the issues raised by the commenters and provide an updated BART determination. The updated BART analysis from CCS is included in Appendix B.4.b.¹⁸⁹ The Department's BART determination is included in Appendix F.

8.3 BART Summary

Coal Creek Station Unit 1 and Unit 2 are identical tangentially-fired pulverized coal boilers combusting North Dakota lignite coal. The existing NO_x control equipment for both Unit 1 and Unit 2 is LNC3+. LNC3+ is a combination of closed coupled overfired air, separated overfired air, and low NO_x burners (LNC3) in conjunction with DryFinishingTM and expanded overfire air registers (the "+" in LNC3+). LNC3+ was operational on Unit 2 in 2010 and on Unit 1 in 2020. The existing NO_x controls were determined to be BART for Unit 1 and Unit 2 at CCS. The BART limit determined by the Department for each unit is a limit of 0.15 pounds per million Btu of heat input on a 30-day rolling average basis. This is lower than the proposed BART limit of 0.17 pounds per million Btu included in the "Supplemental No. 2" update provided in January 2013. The limit is to be achieved using the existing LNC3+ controls.

¹⁸⁸ Available at: <https://www.regulations.gov/>, Docket ID: EPA-R08-OAR-2010-0406-0427

¹⁸⁹ Appendix B, PDF page 576. Appendix B.4.b also contains CCS's four factor analysis for Round 2 planning.

The selection of LNC3+ as BART is supported by the information contained in Appendix F. The key supporting factors are: LNC3+ is cost feasible at \$700 per ton of NO_x reduced while providing a 28% reduction from the baseline emissions rate, and LNC3+ has negligible energy and non-air quality environmental impacts. Cost, technical feasibility concerns, added non-air quality environmental impacts, and limited modeled visibility improvement were the key factors in eliminating the consideration of add-on SNCR or SCR for CCS.

The proposed permit to construct putting in place the enforceable NO_x emissions limits is included in Appendix F.2. The proposed limit of 0.15 lb NO_x per MMBtu on a 30-day rolling average is less than the presumptive BART limit established in Table 1 of the BART guidelines for tangential-fired lignite units. Table 1 of the guidelines indicates a presumptive BART limit of 0.17 lb NO_x per MMBtu on a 30-day rolling average.¹⁹⁰

¹⁹⁰ 40 CFR Part 51 Appendix Y, Guidelines for BART Determinations under the RHR

9 §51.308(g) – Five-Year Progress Report

9.1 Federal Requirements

Section 169(A) of the Clean Air Act (CAA) establishes the national visibility goal of “the prevention of any future, and the remedying of any existing, impairment of visibility in CIAs which impairment results from manmade air pollution.” Based on the requirements of Section 169(A), the Department developed a State Implementation Plan (SIP) to address the national visibility goal. The Regional Haze SIP for the first planning implementation period was submitted to the U.S. Environmental Protection Agency (EPA) in March 2010.

The RHR in 40 CFR 51.308(g) requires that each state develop periodic progress reports describing their progress toward the RPGs established in the RH SIP. The first periodic progress report is due to EPA five years after submittal of the RH SIP for the first planning implementation period with the next Progress Report due January 31, 2025 (40 CFR 51.308(g)). In 40 CFR 51.308(f)(1)(iv), EPA requires states to address the progress made towards the national visibility goal by stating:

“Progress to date for the most impaired and clearest days. Actual progress made towards the natural visibility condition since the baseline period, and actual progress made during the previous implementation period up to and including the period for calculating current visibility conditions, for the most impaired and for the clearest days”.

In its document “Guidance on Regional Haze State Implementation Plans for the Second Planning Implementation Period” EPA states the required progress report elements:

“Section 51.308(f)(5) of the Regional Haze Rule requires a state to address in the plan revision the requirements of paragraphs 51.308 (g)(1) through (5), so that the plan revision due in 2021 will serve also as a progress report addressing the period since submission of the progress report for the first planning implementation period. The progress report for the first implementation period was only able to report on visibility levels, emissions, and implementation status up to a date sometime before it was submitted. To fully inform the public and EPA about past implementation activities, we recommend that the 2021 SIP cover a period approximately from the first full year that was not actually incorporated in the previous progress report through a year that is as close as possible to the submission date of the 2021 SIP.”

To comply with this requirement, each section of the rule is addressed separately

- Status of Control Strategies in the Regional Haze SIP (40 CFR 51.308(g)(1))
- Emissions Reductions from the Regional Haze SIP Strategies (40 CFR 51.308(g)(2))
- Visibility Progress (40 CFR 51.308(g)(3))
- Emissions Progress (40 CFR 51.308(g)(4))
- Assessment of Changes Impeding Visibility Progress (40 CFR 51.308(g)(5))

The first periodic report, which was submitted to EPA in January 2015, has not been approved by EPA at the time this SIP revision is being drafted. Therefore, to better inform the public, data is being supplied from 2000–2018 rather than just the last five years.

9.2 Round 1 Background Information

In the RH SIP for the first planning implementation period, it was demonstrated that even if all North Dakota emissions of SO₂ and NO_x were removed, the uniform rate of progress could not be achieved (see RH SIP for the first planning implementation period, Section 8.6.3.3). The Department established RPGs based on its hybrid modeling approach for the first planning period of 16.9 dv for TRNP and 18.9 dv for LWA. However, it should be noted that based on WRAP's modeling approach, the RPGs would be 17.2 dv for TRNP and 19.1 dv for LWA (see first planning implementation period RH SIP, Table 9.14).

Both the Department's modeling approach and WRAP's modeling indicated that significant emissions reductions in North Dakota (60% for SO₂ and 25% for NO_x) would not have a significant impact (≤5%) on the baseline visibility impairment for the 20% haziest days. The reasons for this small improvement are apparent by reviewing Section 3.1 and Appendix C. North Dakota sources contribute a small portion to the ammonium sulfate and ammonium nitrate light extinction in North Dakota's CIAs, meaning even significant changes in emissions are unlikely to significantly improve visibility. The RPGs established in the RH SIP were disapproved by EPA (77 FR 20944) because EPA disagreed with the NO_x BART determination for the Coal Creek Station and the NO_x reasonable progress determination for the Antelope Valley Station. Antelope Valley Station is now in compliance with the FIP NO_x limits. The Department has proposed a new BART limit for Coal Creek Station, included with Section 8 of this SIP revision.

The Department has submitted a SIP revision for Antelope Valley Station, which would replace the FIP for the Antelope Valley Station. On March 12, 2021 EPA proposed to approve the SIP revision submitted by the Department on August 3, 2020 which adopted the FIP requirements. In conjunction with this proposal, EPA also proposed to withdraw the portions of the 2012 FIP which applied to Antelope Valley Station.¹⁹¹

The EPA did not establish new RPGs in terms of deciviews in their FIP for regional haze in North Dakota. Technically, there are no RPGs established for North Dakota's CIAs. Since the proposed SIP revision for Antelope Valley Station will have a small effect on visibility impairment, the RPGs established in the RH SIP for the first planning implementation period will be utilized for this assessment. However, this SIP revision establishes new RPGs based on regional modeling (Section 6.1: Establishment of RPGs).

In order to achieve reasonable progress toward the national visibility goal, the RH SIP for the first planning implementation period relied primarily on SO₂ and NO_x reductions from existing coal fired EGUs. The requirements for the reductions were based on both the BART requirements in 40 CFR 51.308(e) and the reasonable progress requirements in 40 CFR 51.308(d).

In addition to the BART and reasonable progress requirements, the RH SIP for the first planning implementation period relied on Federal programs such as:

¹⁹¹ 86 FR 14055. Available at: <https://www.govinfo.gov/content/pkg/FR-2021-03-12/pdf/2021-04402.pdf>

- Heavy Duty Diesel Engine Standard
- Tier 2 Tailpipe Standards
- Large Spark Ignition and Recreational Vehicle Rule
- Nonroad Diesel Rule
- Industrial Boiler MACT
- NSPS and MACT Standards for Combustion Turbines, Reciprocating and Internal Combustion Engines

The SIP also relies on several on-going State emissions control programs in the North Dakota and non-SIP rules. These include the State's major and minor new source review program, fugitive dust control requirements, open burning restrictions, control requirements for sulfur dioxide and particulate matter from point sources, and State specific requirements for oil and natural gas production facilities. The list of emission control programs provided here is a summary of the RH SIP for the first planning implementation period and may not be comprehensive; please refer to this RH SIP revision for the second planning period for more details (Section 5.3).

9.3 Periodic Progress

9.3.1 Status of Control Strategies in the Regional Haze SIP – §51.308(g)(1)

40 CFR 51.301(g)(1) states that the progress report shall include *"A description of the status of implementation of all measures included in the implementation plan for achieving reasonable progress goals for mandatory Class I Federal areas both within and outside the State."* The EPA expects states to describe: 1) BART and reasonable progress limits for individual sources; and 2) additional control measures that the state relied on to meet the requirements of the regional haze program that were to take effect in the first planning period.

The BART control requirements were implemented as expeditiously as possible but no later than five years after EPA approved the SIP (May 7, 2012). Therefore, different compliance dates applied for different sources and different pollutants. North Dakota's BART and reasonable progress limits have been incorporated into the Title V Permits to Operate for the affected sources except the NO_x limits for Coal Creek Station, see Table 1 in Section 1.3. Coal Creek Station NO_x BART limits are addressed with this SIP revision under Section 8.

For a comparison of individual unit projected 2028 emissions, current representative performance rate, current emissions limits, and current SO₂ and NO_x control devices; see Table 22 for SO₂ (Section 4.2.1.1.1) and Table 23 for NO_x (Section 4.2.1.1.2).

Additional control measures that the state relied on to meet the requirements of the regional haze program that were to take effect in the first planning period are included in Section 5.3. This includes State and Federal regulations and programs.

9.3.2 Emissions Reductions from Regional Haze SIP Strategies – §51.308(g)(2)

The RHR require that a summary of emissions reductions achieved throughout the State through implementation of the control measures in the SIP be included in the periodic report.

Since the baseline period (2000–2004), significant emissions reductions of most visibility impairing pollutants have occurred in North Dakota. The reductions can be attributed to reductions in both the point and mobile source categories. Implementation of new controls at coal fired EGUs and new Federal requirements for on- and off-road engines are the main reasons for the reductions. Sections 4.1.1, 4.1.2, and 4.1.5 show the results of emission inventories for WRAP’s 2002 Plan 02d, and the 2011 and 2017 National Emissions Inventory (NEI), respectively. The 2011 NEI data were the latest available for the initial progress report submitted in January 2015 and the 2017 NEI is included in this SIP revision for informational purposes. With any inventory, a change in estimation methodology or emission factors can greatly change the results. However, as shown in Section 4.2.1, the overall emission reductions at the EGUs, as measured by continuous emission monitors, are real. SO₂ and NO_x reductions from individual coal fired EGUs can be found in Sections 4.2.1.1.1 and 4.2.1.1.2, respectively. The coal fired EGUs were the sources subject to BART and reasonable progress in the first planning period.

The increase in VOC emissions is due primarily to increases in oil and gas area sources and fire events.

9.3.3 Visibility Progress – §51.308 (g)(3)

To satisfy the requirements of 40 CFR 51.308(g)(3), a state must assess the following visibility conditions and changes, with values for most impaired and/or clearest days expressed in terms of 5-years average of the annual values, for each CIA within the State:

- The current visibility conditions for the most impaired and clearest days,
- The difference between the current visibility for the MIDs and the clearest days and the baseline conditions; and
- The change in visibility impairment for the MIDs and the clearest days over the past 5 years.

Visibility impairment in North Dakota’s CIAs on the MIDs is primarily due to ammonium sulfate and ammonium nitrate (Section 5.1.1). This is true whether the visibility metric is the haziest days, MIDs, or clearest days, see Section 3. North Dakota’s SIP for the first implementation period focused primarily on controlling sources of sulfur dioxide and nitrogen oxides which form the ammonium sulfates and ammonium nitrates in the atmosphere, see Section 1.3. Organic carbon aerosols in North Dakota generally originate from fire (wildfire or prescribed burning) and fugitive sources. The Regional Haze SIP demonstrated that controls in-place for sources of fire and fugitive dust were adequate for the first planning period, Section 5.3.2 and 5.3.4.

The contribution of North Dakota sources to visibility impairment in nearby CIAs is shown in Table 39. North Dakota’s CIAs are also included in Table 39. The sulfate and nitrate contributions to impairment in nearby CIAs are generally small, at less than 10%.

Table 39: North Dakota’s Contribution to Species Light Extinction in Nearby Class I Areas

State	Class I Area	Species Light Extinction (Mm ⁻¹)	North Dakota Ammonium Nitrate	North Dakota Ammonium Sulfate
North Dakota	LOST1	39	13%	12%
North Dakota	THRO1	30	9%	8%

State	Class I Area	Species Light Extinction (Mm ⁻¹)	North Dakota Ammonium Nitrate	North Dakota Ammonium Sulfate
Montana	MELA1	35	8%	6%
South Dakota	BADL1	22	2%	5%
South Dakota	WICA1	17	1%	1%
Minnesota	VOYA2	28	2%	1%

The significant emissions reductions achieved by the EGUs in North Dakota equal or exceed those of surrounding states from the first implementation period of the RHR. The emissions reductions achieved in North Dakota likely assisted surrounding states in meeting their RPGs.

9.3.4 Emissions Progress – §51.308(g)(4)

This section of the RHR requires each state to submit an analysis tracking the change over the past 5 years in emissions of pollutants contributing to visibility impairment from all sources and activities within the State. Emissions changes should be identified by type of source of activity. The analysis must be based on the most recent updated emissions inventory, with estimates projected forward as necessary and appropriate to account for emissions changes during the applicable 5-year period.

Section 4.1 provides emissions inventory data for 2002, 2011, 2014, 2017, current representative, and projected future emissions. Discussion on where these data originate is also included in Section 4.1.

9.3.5 Assessment of Changes in Anthropogenic Emissions Impeding Visibility Progress – §51.308(g)(5)

This section of the RHR requires “an assessment of any significant changes in anthropogenic emissions within or outside the State that have occurred since the period addressed in the most recent plan...and whether they have limited or impeded progress in reducing pollutant emissions and improving visibility.” The most obvious source category where emissions have increased in North Dakota is the oil and natural gas production sector. Beginning in 2008, development of the Bakken formation in North Dakota increased significantly. In 2008 there was an average of 3,869 active producing wells. The number average producing wells increased to 5,546 in 2011 and to 15,412 in 2019. In 2028, this number is projected to be at least 24,000. With the increase in production, emissions increased not only from oil and gas well operations, but also from well development, local infrastructure development, increased traffic, transportation of the oil and natural gas, treatment of the oil and gas, well maintenance, oil and condensate storage, and flaring of the natural gas when a pipeline or capacity within the pipeline is not available. Another, but less obvious source impeding visibility progress is North Dakota’s population increase. North Dakota’s pollution has increased by nearly 16% since 2010.¹⁹² A significant portion of the

¹⁹² Available at: <https://apnews.com/article/census-2020-north-dakota-1750bbfe4ffc3749e71900ab63e08298#:~:text=The%20state's%20rate%20of%20growth,total%20population%20to%20779%2C094%20people>. (Last visited May 19, 2021)

increase in attributable to the support needed for the operation of the Bakken in the western North Dakota.

Emissions changes from the oil and gas sector have been quantified and are addressed in Section 4.3.1. The pollutants with the most significant increase are VOCs and NO_x. Bakken crude (from the Bakken, Sanish and Three Forks formations) typically contains a high concentration of lighter end components which have the potential to produce increased flash and fugitive hydrocarbon emissions. Flash emissions are the hydrocarbons emitted when the pressure of the crude oil is decreased, or the temperature is increased. In May 2011, the Department published its “Bakken Pool Oil and Gas Production Facilities Air Pollution Control Permitting and Compliance Guidance”.¹⁹³ The Bakken Guidance established the expected air pollution control requirements for oil and gas production from the Bakken formation in order to comply with NDAC 33.1-15-07, Control of Organic Compounds Emissions and NDAC 33.1-15-20, Control of Emissions from Oil and Gas Well Production Facilities. The guidance is applicable to all areas of North Dakota except tribal areas. On March 22, 2013, the EPA finalized a Federal Implementation Plan (FIP) which established air pollution control requirements for oil and gas well production facilities on the Fort Berthold Indian Reservation. Both the North Dakota Air Pollution Control Rules, the Bakken Guidance, and the FIP were expected to reduce emissions of volatile organic compounds. Although emissions of volatile organic compounds have increased, they would likely have increased more substantially without these air pollution control requirements. Furthermore, it appears these emissions are having little effect on visibility in the CIAs, see Section 3.

Similar to VOC emissions, NO_x emissions from area oil and gas facilities have increased as a result of the Bakken development. Much of the increase is attributed to the well drilling and completion phases of a wellsite. Another potentially significant source of emission is from the flaring of associated gas. As stated in Section 5.2.11, the North Dakota Industrial Commission adopted a policy to reduce flaring in the oil fields. This plan took effect beginning June 1, 2014. The policy was updated in September 2020.¹⁹⁴ This policy has been helpful in reducing the percentage of produced gas being flared. Figure 43 displays the amount and percent of flared gas since the Bakken development.

Since the baseline (2002), total Anthropogenic NO_x emissions have not changed significantly (2002 vs. RepBase). North Dakota EGUs achieved over 41,000 tons of NO_x reductions from 2002 to RepBase. These reductions were displaced by the increase of over 57,000 tons of NO_x attributable to the area source oil and gas development. North Dakota is anticipating a reduction of over 50,000 tons of NO_x from the current levels by 2028. These projections come from decreases in the EGU sector, area source oil and gas, and on-road and non-road engines.

¹⁹³ Available at: https://www.deq.nd.gov/publications/AQ/policy/PC/20110502_OilGas_Permitting_Guidance.pdf (Last visited December 22, 2020)

¹⁹⁴ Available at: https://www.dmr.nd.gov/oilgas/112018GuidancePolicyNorthDakotaIndustrialCommissionorder24665_2.pdf (Last visited December 22, 2020)

The five-year rolling average nitrate extinction at TRNP has decreased 24% from the baseline (2002–2004) to the 2014-18 period on the 20% MIDs and 42% on the clearest days (Section 3.2.5). At LWA, nitrate extinction has decreased 22% on the MIDs and 4% on the clearest days (Section 3.2.5).

Although ozone is not a visibility impairing pollutant, the increase of volatile organic compounds and nitrogen oxides emissions have been speculated to cause increased ozone concentrations. The Department has established ozone monitoring stations at TRNP-SU, TRNP-NU, LWA and at various other sites across North Dakota. The monitor data indicates that ozone design concentrations at each CIA have remained stable since the baseline period (see Air Quality in North Dakota section). The increase in volatile organic compounds and nitrogen oxides from the oil and gas sector does not appear to be affecting ozone concentrations in the CIAs or any other regions of North Dakota.

Appendix A – Department Four-Factor Analyses

A.1 – Coyote Station

1 Introduction and Representative Operations

Otter Tail Power Company – Coyote Station (Coyote) is a single unit electrical generating utility (EGU) with a capacity to produce approximately 450 megawatts (MW) per hour of electricity. The boiler is a Babcock and Wilcox cyclone fired boiler with a heat input capacity of 5,800 million British thermal units (MMBtu) per hour. Coyote commenced operation in 1981. Coyote is located in Mercer County about three miles southwest of the town of Beulah, North Dakota. Coyote is a mine-mouth power plant which receives coal from North American Coal Company – Coyote Creek Mine.

The average annual amount of North Dakota lignite coal combusted at Coyote from 2009 through 2018 was 2.2 million tons. See Table 1 for detailed information.

Table 1: Yearly Coal Combusted (tons)

Year	Coal Combusted (tons)
2009	2,032,400
2010	2,445,773
2011	2,444,280
2012	1,824,595
2013	2,105,090
2014	2,248,483
2015	1,959,351
2016	2,011,974
2017	2,154,856
2018	2,501,698
Average	2,172,850

Over the same 10-year period (2009–2018), Coyote operated at a 60% annual capacity factor (ACF), as determined on an actual heat input basis. Future operations are expected to be consistent with this 10-year period and the 60% annual capacity factor was used when calculating the baseline and future projected emissions discussed in Section 2.

Table 2 displays the operational information from 2009–2018. The ACF is calculated by dividing the actual heat input by the maximum potential heat input of 50.8×10^6 MMBtu per year.

Table 2: Utilization and Annual Capacity Factor

Year	Actual Heat Input (MMBtu/yr)	Annual Capacity Factor (ACF)
2009	28,835,063	0.57
2010	35,201,254	0.69
2011	35,579,248	0.70
2012	27,008,173	0.53
2013	31,206,229	0.61
2014	32,197,996	0.63

Year	Actual Heat Input (MMBtu/yr)	Annual Capacity Factor (ACF)
2015	22,757,213	0.45
2016	27,102,662	0.53
2017	29,849,117	0.59
2018	34,550,493	0.68
Average	30,428,745	0.60

2 NO_x and SO₂ Emissions Controls and History

Coyote commenced operation in 1981. Coyote was not a BART eligible source since construction of the facility commenced after the August 7, 1977 end date for facilities in existence. Coyote was, however, subject to the reasonable progress requirements during the first round of the regional haze program.

2.1 NO_x

2.1.1 NO_x Emissions Controls

Coyote's cyclone boiler is equipped with separated overfire air (SOFA) to reduce the formation of NO_x during the combustion process. The Department reached an agreement with Coyote for the installation of SOFA during the first planning period of the regional haze program. Under Permit to Construct No. PTC10008, Coyote was required to install SOFA by July 1, 2018 and meet an emissions limit of 0.50 pounds NO_x per MMBtu on a 30-day rolling average. This construction permit was incorporated as Appendix A.4 to the July 2011 Amendment No. 1 to the North Dakota State Implementation Plan for Regional Haze. On June 15, 2016 Coyote commenced start-up of the SOFA system to comply with the requirements of Permit to Construct No. PTC10008. No add-on NO_x controls have been installed at Coyote.

2.1.2 NO_x Emissions History

The time period from July 2016 through December 2018 was used to determine the NO_x baseline emissions rate from Coyote. This information is displayed in Table 3.

Table 3: Annual NO_x emissions rate

Year	Emissions Rate (lb/MMBtu)
2016	0.50
2017	0.42
2018	0.45
Average	0.46

The average emissions rate of 0.46 lb NO_x per MMBtu is representative of future expected operations. This value is used as the starting point when determining the cost of compliance for the add-on controls evaluated in Section 3.2.

2.2 SO₂

2.2.1 SO₂ Emissions Controls

Coyote is equipped with dry flue gas desulfurization (DFGD) and a fabric filter (FF) baghouse for SO₂ and particulate matter control. The DFGD and FF baghouse were installed during the construction of the facility and have not been significantly modified since. Coyote was not required to install any SO₂ controls during the first round of the regional haze program.

2.2.2 SO₂ Emissions History

The time period from January 2013 through December 2018 was used to determine the SO₂ baseline emissions rate from Coyote. 2015 was removed from the baseline period since Coyote experienced operational issues in 2015 and this year was not considered representative of normal operations.¹ This information is displayed in Table 4.

Table 4: Annual SO₂ emissions rate

Year	Emissions Rate (lb/MMBtu)
2013	0.81
2014	0.79
2015 ^A	0.77
2016	0.88
2017	0.90
2018	0.86
Average	0.85

^A Not included in average.

3 NO_x Analysis

3.1 NO_x Technologies

The reasonable progress controls evaluated by Coyote are listed in Table 5. Performance rate and expected annual emissions are included for each control technology that was determined to be technically feasible. Expected annual emissions were calculated using the performance rate, potential heat input, and the ACF (Table 2).

Table 5: Reasonable Progress NO_x Controls

Control Technology	Control Technology Abbreviation	Performance Rate (lb/MMBtu)	Emissions (tons/year)
Separated Overfire Air (baseline)	SOFA	0.46	7,015
Combustion Optimization	--	0.42	6,405
Selective Non-Catalytic Reduction	SNCR	0.28	4,270
SNCR + Rich Reagent Injection	SNCR + RRI	0.20	3,050
Selective Catalytic Reduction	SCR	--	--

¹ Appendix B.1.b, p. 4-1. PDF page 33.

3.1.1 Combustion Optimization

Optimization of the combustion process through tuning the cyclone boiler has a small beneficial impact on reducing the formation of NO_x emissions. Tuning the boiler can lower the baseline performance rate from 0.46 to 0.42 lb NO_x per MMBtu, reducing the NO_x emission by approximately 9%. There is no cost associated with this technology since tuning the boiler primarily deals with optimization of the air-to-fuel ratio into the boiler. Combustion optimization would occur prior to the installation of any add-on controls.

3.1.2 Selective Non-Catalytic Reduction (SNCR)

Installation of SNCR post combustion add-on control equipment has a significant impact on removing NO_x emissions from the flue gas. SNCR is anticipated to provide approximately a 39% reduction in NO_x emissions from the baseline scenario, lowering the expected performance rate from 0.46 to 0.28 lb NO_x per MMBtu. Installation of SNCR on Coyote's cyclone boiler is technically feasible and will be evaluated further.

3.1.3 Rich Reagent Injection (RRI)

RRI is a technology similar to SNCR, where a nitrogen-containing additive is injected to promote NO_x removal. The main differences are RRI is physically located in the lower part of the furnace near the cyclone boilers where SNCR is further downstream and RRI is done through one injection port where SNCR typically has many ports.

RRI is technically feasible at high load operations but has limitations at low loads due to the difficulty in maintaining the proper air-to-fuel ratio. RRI is typically installed after SNCR is installed for additional NO_x control. RRI is not commonly used as an individual NO_x control in lieu of SNCR since SNCR is better and more established. Therefore, RRI is evaluated as add-on control in addition to SNCR but not as a stand-alone add-on control by itself.²

Installation of SNCR + RRI has a significant impact on removing NO_x emissions from the flue gas. SNCR + RRI is anticipated to provide approximately a 57% reduction in NO_x emissions from the baseline scenario, lowering the expected performance from 0.46 to 0.20 lb NO_x per MMBtu. Installation of SNCR + RRI on Coyote's cyclone boiler is technically feasible and will be evaluated further.

3.1.4 Selective Catalytic Reduction (SCR)

SCR is post combustion add-on control equipment. SCR, when feasible, typically has the greatest impact on removing NO_x emissions from a flue gas stream. SCR is traditionally installed in one of three configurations: high-dust, low-dust, or tail-end. During the first regional haze program planning period in North Dakota the Department determined that installation of SCR, in any configuration, is not a technically feasible control technology since it has not been demonstrated in practice on North Dakota lignite coal.³ The determination of technical feasibility has not changed since the first regional haze program planning period; therefore, SCR will not be evaluated further.

² Appendix B.1.b, p. 5-26. PDF page 60.

³ North Dakota State Implementation Plan for Regional Haze, March 3, 2010, Appendix B.5.

3.2 Step 1 – Cost of Compliance

The cost of compliance and incremental cost for the reasonable progress controls are listed in Table 6.

Table 6: NO_x Cost of Compliance and Incremental Cost of Compliance

Control Technology	Performance Rate (lb/MMBtu)	Annual Emission Reduction (tpy)	Annualized Total Cost (\$)	Cost of Compliance (\$/ton)	Incremental Cost of Compliance (\$/ton)
SOFA (Baseline)	0.46				
SOFA Optimization	0.42	610	0	0	
SNCR + Optimization	0.28	2,745	4,753,933	1,732	
SNCR + RRI + Optimization	0.20	3,965	12,690,135	3,200	6,505

A detailed breakdown of the costs listed in Table 6 can be found in Coyote’s submitted four factors analysis.⁴ The Department has reviewed these costs and believes them to be accurate.

As displayed in Table 6 and stated in Section 3.1.1, there is no cost associated with optimization of the combustion process. The 0.04 lb NO_x per MMBtu improvement over the baseline performance would be required as the first step for any of the remaining technologies evaluated.

If SNCR is installed in conjunction with combustion optimization, a performance rate improvement of 0.18 lb NO_x per MMBtu could be achieved. This equates to a potential reduction of approximately 2,750 tons NO_x per year from the baseline emissions. Fiscally, SNCR installation requires an estimated annualized cost of \$4.75 million and NO_x removal cost of roughly \$1,700 per ton.

The addition of RRI to SNCR and combustion optimization results in an expected performance improvement of 0.26 lb NO_x per MMBtu from the baseline performance rate. This equates to a potential reduction of approximately 3,970 tons NO_x per year from the baseline emissions. Fiscally, SNCR + RRI installation requires an estimated annualized cost of \$12.7 million and NO_x removal cost of \$3,200 per ton. To determine the appropriate reasonable progress control selection between SNCR and SNCR + RRI, the Department determined the stand-alone cost of installing RRI after SNCR is installed. This stand-alone cost is referred to as the incremental cost of compliance. Incremental cost of compliance is a key factor to consider when selecting reasonable progress controls since it details the cost effectiveness of RRI installation. A cost breakdown indicates approximately \$8 million of the annualized cost is attributable to the installation of RRI, and results in the potential for an additional 1,220 tons of NO_x to be removed. This results in an incremental cost of compliance of roughly \$6,500 per ton.

3.3 Step 2 – Time Necessary for Compliance

A summary of the anticipated timelines for the installation of controls is provided in Table 7.

⁴ Appendix B.1.b, Appendix C. PDF page 102.

Table 7: Time Required for NO_x Controls

Control Technology	Total time after SIP approval (months)
SOFA Optimization	0
SNCR + Optimization	22
SNCR + RRI + Optimization	22

3.4 Step 3 – Energy and Non-Air Quality Environmental Impacts

3.4.1 Energy

Small changes to onsite energy consumption are likely to be experienced with the implementation of any add-on NO_x controls.⁵ The impact not significant enough to eliminate add-on NO_x controls as a control option.

3.4.2 Non-Air Quality Environmental Impacts

SNCR use ammonia as a reagent. Ammonia slip emissions will result in the flue gas stream on the exhaust side of the control equipment due to the operation of the SNCR (~10 ppm). The ammonia slip emissions from the operation of SNCR would likely combine with the dry FGD solids. The ammoniated dry FGD solids would require that further safety precautions are taken for Coyote staff who perform maintenance on the ash handling system or staff who dispose of waste.

Similar to the energy impacts for add-on NO_x controls, the non-air quality environmental impacts are not significant enough to eliminate add-on NO_x controls as a control option.

3.5 Step 4 – Remaining Useful Life

Based on the information provided to the Department, Coyote is expected to operate beyond the life of the control equipment. Therefore, remaining useful life was not considered.

4 SO₂ Analysis

4.1 SO₂ Technologies

The reasonable progress controls that were evaluated by Coyote are listed in Table 8. Performance rate and expected annual emissions are included for each control technology that was determined to be technically feasible. Expected annual emissions were calculated using the performance rate, potential heat input, and the ACF (Table 2).

Table 8: Reasonable Progress SO₂ Controls

Control Technology	Control Technology Abbreviation	Performance Rate (lb/MMBtu)	Emissions (tons/year)
Dry Flue Gas Desulfurization (baseline)	DFGD	0.85	12,963
Dry Sorbent Injection	DSI	0.58	8,845
Dry Flue Gas Desulfurization Improvements	DFGD Improvements	0.5	7,625

⁵ Appendix B.1.b, p. 8-2 – 8-4. PDF page 84-86.

Control Technology	Control Technology Abbreviation	Performance Rate (lb/MMBtu)	Emissions (tons/year)
DFGD Improvements + DSI	DFGD Improvements + DSI	0.33	5,033
Absorber Replacement	--	0.09	1,373
New Dry Flue Gas Desulfurization and Fabric Filter	DFGD + FF	0.09	1,373
Wet Flue Gas Desulfurization	WFGD	0.06	915

4.1.1 Dry Sorbent Injection (DSI)

DSI is a proven technology which provides a moderate reduction of SO₂ in the flue gas stream. Sorbent is injected into the ductwork downstream of the boiler and upstream of the existing DFGD unit. Sorbent reacts with SO₂ to form particulate matter which is removed in the downstream fabric filter. DSI lowers the concentration of SO₂ entering the DFGD unit, allowing for an overall increase in SO₂ removal. Calcium- and sodium-based sorbents are the most common to reduce SO₂, each of which has pros and cons depending on the site and control equipment characteristics. The existing DFGD unit at Coyote utilizes a calcium-based system (hydrated lime); therefore, using a calcium-based sorbent is the most logical. This removes the potential for new chemical (sodium) constituents into the system which may adversely affect the existing scrubber operations.

DSI is anticipated to provide approximately a 32% reduction in SO₂ emissions from the baseline scenario, lowering the expected performance rate from 0.85 to 0.58 lb SO₂ per MMBtu. Adding DSI to the existing DFGD unit is technically feasible and will be evaluated further.

4.1.2 Flue Gas Desulfurization (FGD) Improvements

FGD Improvements are grouped into two categories, operational improvements and equipment upgrades. The operational improvements evaluated consisted of increasing the lime quality, increasing the stoichiometric ratio of calcium to sulfur (Ca:S) by increasing lime quantity, and lowering the absorber outlet temperature closer to the saturation point. The equipment upgrades consisted of atomizer replacement, slaker replacement, adding an absorber module, and replacing the existing absorber module.

For each of the operational improvements and equipment upgrades evaluated, the only technically feasible options are increasing the stoichiometric ratio of Ca:S coupled with atomizer replacement and replacing the existing absorber module. Replacing the absorber module is evaluated independent in Section 4.1.4. For complete discussion of the options determined to be technical infeasible, see Appendix B.1.b, pages 5-4 through 5-12.

For Coyote, increasing the Ca:S stoichiometry is best accomplished by increasing the quantity of fresh lime introduced into the system. Engineering testing was conducted in October of 2018 to determine the impact this type of stoichiometry adjustment could have on lowering SO₂ emissions. During the testing, it was determined that increasing the Ca:S ratio could achieve a rate as low as 0.50 lb SO₂ per MMBtu. If an increased stoichiometric ratio were to be required on a permanent basis, the existing dry scrubber atomizer nozzles would also need to be replaced from an eight

nozzle design to a twelve nozzle design to achieve a more optimal slurry spray and decrease the potential for operational issues which may cause unit downtime.

Ca:S stoichiometry adjustments coupled with the atomizer replacement is anticipated to provide approximately a 41% reduction in SO₂ emissions from the baseline scenario, lowering the expected performance rate from 0.85 to 0.50 lb SO₂ per MMBtu. Increasing the Ca:S stoichiometry coupled with the atomizer replacement at the existing DFGD unit is technically feasible and will be evaluated further.

4.1.3 FGD Improvements with DSI

The technologies evaluated in Section 4.1.1 (DSI) and Section 4.1.2 (FGD Improvements) could be implemented together, resulting in a more significant overall reduction of SO₂. Implementation of FGD Improvements with DSI is anticipated to provide a 61% reduction from the baseline scenario, lowering the performance rate from 0.85 to 0.33 lb SO₂ per MMBtu. Implementation of FGD Improvements and DSI is technically feasible and will be evaluated further. It should be noted that additional flow modeling and field testing would need to be performed to ensure this performance level could be achieved and maintained without adversely affecting plant operability.

4.1.4 Absorber Replacement

Replacing the existing absorber module is technically feasible and could provide a significant improvement in reducing SO₂ emissions. Coyote originally indicated there is a no physical space for installation of a new absorber, making it an infeasible option since an approximate 12-month downtime was estimated for the replacement to occur. This inherently made an absorber replacement a less attractive control option. Since the original information was provided, Coyote submitted an analysis on June 8, 2020 indicating they could implement an absorber replacement.⁶

The absorber module replacement is anticipated to provide a 89% reduction from the baseline scenario, lowering the performance rate from 0.85 to 0.09 lb SO₂ per MMBtu. Replacement of the absorber module is technically feasible and will be evaluated further.

4.1.5 New Dry FGD (DFGD) and Fabric Filter (FF)

Two types of new DFGD systems were evaluated at Coyote, a spray dryer absorber (SDA) and a circulating dry scrubber (CDS). Each of these systems is technically feasible, commercially available, and would require significant modifications to the facility. The engineering evaluation determined the CDS would outperform the SDA at Coyote.⁷ A new SDA/FF is anticipated to be able to achieve a performance rate of 0.16 lb SO₂ per MMBtu. A new CDS/FF is anticipated to be able to achieve a performance rate of 0.09 lb SO₂ per MMBtu. Given the lower performance rate with the CDS/FF system, the Department will focus the remaining analysis on the CDS/FF system. Implementation of a CDS/FF system represents an 89% reduction from the baseline scenario. Replacing the existing DFGD unit with a new CDS/FF is technically feasible. However, this option will not be evaluated further since Coyote has submitted additional information indicating an absorber replacement could

⁶ Appendix B.1.b. PDF page 216

⁷ Appendix B.1.b, p. 5-18. PDF page 52.

achieve the same performance rate of 0.09 lb SO₂ per MMBtu at less than half the cost of a new CDS/FF.⁸

4.1.6 Wet FGD (WFGD)

Replacing the DFGD with a WFGD system located downstream of the existing FF was the most effective and costly SO₂ control option evaluated. WFGD systems are well established in and are operated on many coal-fired power plants firing medium to high sulfur coal. All WFGD systems use an alkaline slurry that reacts with SO₂ to form calcium sulfite and calcium sulfate. A WFGD system designed for Coyote is anticipated to be able to achieve a performance rate of 0.06 lb SO₂ per MMBtu, or a 93% reduction from the baseline emissions scenario. Installation of a new WFGD system is technically feasible and will be evaluated further.

4.2 Step 1 – Cost of Compliance

The cost of compliance and incremental cost of compliance for the reasonable progress controls are listed in Table 9.

Table 9: SO₂ Cost of Compliance and Incremental Cost of Compliance

Control Technology	Performance Rate (lb/MMBtu)	Annual Emission Reduction (tpy)	Annualized Total Cost (\$)	Cost of Compliance (\$/ton)	Incremental Cost of Compliance (\$/ton)
DFGD/FF (Baseline)	0.85				
DSI + Existing FGD	0.58	4,118	12,371,000	3,004	
FGD Improvements	0.50	5,338	2,085,000	391	-8,431
DSI + FGD Improvements	0.33	7,930	14,456,000	1,823	4,772
Absorber Replacement	0.09	11,590	21,122,000	1,822	1,821
WFGD	0.06	12,048	49,094,000	4,075	61,139

A detailed breakdown of the costs listed in Table 9Table 6 can be found in Coyote’s submitted four factors analysis.⁹ The Department has reviewed these costs and believes them to be accurate.

There are many options available for Coyote to reduce SO₂ emissions. The control costs vary drastically in annualized cost and significantly in effectiveness. A summary of each option evaluated is provided in the following paragraphs.

Installation of DSI would provide a potential 32% reduction in emissions from the baseline scenario. This results in approximately 4,100 tons of SO₂ reduced at an annualized cost approximately \$12.3 million, equating to \$3,000 per ton of SO₂ reduced. The FGD Improvements discussed in the following paragraph provide for greater emissions reductions at a lower cost, therefore, stand-alone installation of DSI on the existing DFGD unit is not considered further for reasonable progress.

FGD Improvements, specifically the Ca:S stoichiometric adjustments, provide a potential 41% reduction in emissions from the baseline scenario. This results in approximately 5,300 tons of SO₂

⁸ Appendix B.1.b. PDF page 220.

⁹ Appendix B.1.b. Appendix B. PDF page 94.

reduced at an annualized cost of approximately \$2 million, equating to approximately \$400 per ton of SO₂ reduced. A benefit to this controls option is the facility can take advantage of upgrading existing equipment at a low capital cost compared to replacement of equipment at high capital costs. Also, as stated in Section 4.3, FDG Improvements could be implemented very quickly providing for a more immediate reduction in SO₂ emissions from the facility.

FGD improvements coupled with installation of DSI would provide a 61% reduction in emissions from the baseline scenario. This results in roughly 7,900 tons of SO₂ reduced at an annualized cost of approximately \$14.5 million, equating to \$1,800 per ton of SO₂ reduced. Since upgrading the FGD is recommended prior to installation of DSI, the incremental effectiveness of each individual control was reviewed. Consistent with the FGD improvements discussed in above paragraph, roughly 5,300 tons of the 7,900 tons reduced are attributable to the FGD improvements at a cost of approximately \$400 per ton. The remaining 2,600 tons reduction is attributable to the DSI installation at an incremental cost of \$4,800 per ton. FGD improvements are expected to lower the SO₂ performance rate from 0.85 to 0.50 lb SO₂ per MMBtu and DSI would further lower this from 0.50 to 0.33 lb SO₂ per MMBtu. In other words, Coyote could reduce the baseline emission rate by 0.35 lb SO₂ per MMBtu at a cost of \$400 per ton and further reduce the rate by 0.17 lb SO₂ per MMBtu at a cost of \$4,800 per ton.

Replacing the existing absorber with a new absorber would provide an 89% reduction in emissions from the baseline scenario. This results in approximately 11,600 tons of SO₂ reduced at an annualized cost of \$21.1 million, equating to roughly \$1,800 per ton of SO₂ reduced. This control option provides for a major reduction in SO₂ at a capital cost and high annualized cost.

Replacing the existing DFGD unit with a new WFGD unit would provide for an 93% reduction in emissions from the baseline scenario. This results in approximately 12,000 tons of SO₂ reduced at an annualized cost of \$49 million, equating to \$4,000 per ton of SO₂ reduced. This control option provides for a major reduction in SO₂ at a capital cost and high annualized cost. To determine if the limited improvement from the absorber replacement to a WFGD unit was viable considering the increased annualized cost, the incremental cost effectiveness between the two options was calculated. This incremental cost effectiveness was determined to be approximately \$61,100 per ton, meaning the addition 0.03 lb SO₂ per MMBtu improvement (0.09 – 0.06) comes at an expensive cost. Since the installation of a new WFGD unit would not significantly improve the SO₂ performance rate (over absorber module replacement), the WFGD will not be considered for reasonable progress.

Of the options evaluated, three options remain on the table as potentially reasonable controls based on cost. These include existing FGD improvements, existing FGD improvements coupled with DSI, and replacement of the existing absorber module.

4.3 Step 2 – Time Necessary for Compliance

A summary of the anticipated timelines for the installation of controls is provided in Table 10.

Table 10: Time Required for SO₂ Controls

Control Technology	Total time after SIP approval (months)
DSI + Existing FGD	18
FGD Improvements	0

Control Technology	Total time after SIP approval (months)
DSI + FGD Improvements	18
Absorber Replacement	32
WFGD	56

4.4 Step 3 – Energy and Non-Air Quality Environmental Impacts

4.4.1 Energy

Small changes to onsite energy consumption are likely to be experienced with the implementation of any SO₂ control options.¹⁰ The impacts are not significant enough to eliminate and SO₂ controls as viable control options.

4.4.2 Non-Air Quality Environmental Impacts

Similar to the energy impacts for SO₂ controls, any non-air quality environmental impacts are not significant enough to eliminate additional SO₂ controls as a viable option.¹¹

4.5 Step 4 – Remaining Useful Life

Based on the information provided to the Department, Coyote is expected to operate beyond the life of the control equipment. Therefore, remaining useful life was not considered.

¹⁰ Appendix B.1.b, p. 8-2 – 8-4. PDF page 84-86.

¹¹ Appendix B.1.b, p. 8-2 – 8-4. PDF page 84-86.

A.2 – Basin AVS

1 Introduction and Representative Operations

Basin Electric Power Cooperative (Basin) – Antelope Valley Station (AVS) is a two-unit electrical generating utility (EGU). Each unit has the capacity to produce approximately 470 megawatts (MW) per hour of electricity. Unit 1 and Unit 2 are identical Combustion Engineering boilers firing pulverized lignite coal tangentially. Unit 1 and Unit 2 each have a heat input capacity of 6,275 MMBtu per hour. Unit 1 began commercial operation in 1984. Unit 2 began commercial operation in 1986. AVS is located in Mercer County about eight miles northwest of the town of Beulah, North Dakota and approximately six miles north of US Highway 200. AVS receives most of its lignite coal from the coal that is too fine-grained to be used by the Great Plains Synfuels Plant (GPSP). GPSP is located just south of AVS. The remaining coal is delivered from the nearby Freedom Mine, which is located approximately two miles north of AVS.

The average annual amount of North Dakota lignite coal combusted at AVS from 2009 through 2018 was approximately 5.3 million tons. See Table 1 for detailed information.

Table 1: Yearly Coal Combusted (tons)

Year	Unit 1 (tons)	Unit 2 (tons)
2009	2,908,708	2,876,852
2010	3,017,251	2,435,302
2011	1,899,776	2,642,530
2012	2,732,031	2,660,454
2013	2,804,599	2,369,861
2014	2,332,119	2,583,418
2015	2,736,138	2,833,973
2016	2,797,996	2,184,054
2017	2,442,876	2,826,520
2018	2,809,117	2,628,612
Average	2,648,061	2,604,158
Combined Average	5,252,219	

Over the same 10-year period (2009–2018), AVS operated at a 63% annual capacity factor (ACF), as determined on an actual heat input basis. Based on information provided to the North Dakota Department of Environmental Quality, Division of Air Quality (Department), future operations are expected to be consistent with this 10-year period and the 63% annual capacity factor was used when calculating the baseline and future projected emissions discussed in Section 2.

Table 2 displays the operational information from 2009–2018. The ACF is calculated by dividing the actual heat input by the maximum potential heat input of 55.0×10^6 MMBtu per year.

Table 2: Utilization and Annual Capacity Factor

Year	Unit 1 Heat Input (MMBtu/yr)	Unit 2 Heat Input (MMBtu/yr)	Unit 1 Annual Capacity Factor	Unit 2 Annual Capacity Factor
2009	38,437,954	37,867,178	0.70	0.69

Year	Unit 1 Heat Input (MMBtu/yr)	Unit 2 Heat Input (MMBtu/yr)	Unit 1 Annual Capacity Factor	Unit 2 Annual Capacity Factor
2010	39,571,458	31,668,162	0.72	0.58
2011	24,197,378	36,027,754	0.44	0.66
2012	35,197,379	35,877,026	0.64	0.65
2013	36,715,597	33,019,271	0.67	0.60
2014	31,118,421	36,431,873	0.57	0.66
2015	37,115,552	39,565,968	0.68	0.72
2016	37,148,044	29,420,896	0.68	0.54
2017	30,310,984	37,550,654	0.55	0.68
2018	34,370,105	35,494,838	0.63	0.65
Average	34,418,287	35,292,362	0.63	0.64
		Combined Average	0.63	

2 NO_x and SO₂ Emissions Controls and History

AVS commenced operation in 1984 when Unit 1 was started up. As is stated above, Unit 2 was started up in 1986. AVS was not a BART eligible source since construction of the facility commenced after the August 7, 1977 end date for “facilities in existence”. AVS was, however, subject to the reasonable progress requirements during the first round of the regional haze program.

During the first round of the regional haze program, the Department determined that no NO_x or SO₂ controls were required for AVS Unit 1 or AVS Unit 2.¹ However, the United States Environmental Protection Agency (EPA) disapproved the Department’s determination² and promulgated a Federal Implementation Plan (FIP)³, which required that a separated overfire air and low-NO_x concentric firing system (SOFA/LNCFS) be installed on AVS Unit 1 and Unit 2. The FIP also required that a new NO_x emission limit of 0.17 lb/MMBtu (30-day rolling average) be established for AVS Unit 1 and Unit 2. The FIP required that the NO_x control technologies be installed by July 31, 2018 on both Unit 1 and Unit 2.⁴

2.1 NO_x

2.1.1 NO_x Emissions Controls

The overfire air pollution control system, which was operational during the decision-making process of the first round of the regional haze program, was retired from Unit 1 on May 27, 2014 and replaced with SOFA/LNCFS on May 28, 2014. The overfire air system was retired from Unit 2 on June 10, 2016 and replaced with SOFA/LNCFS on June 11, 2016. The current air pollution control system operating on both Unit 1 and Unit 2 includes SOFA/LNCFS.

³ <https://www.federalregister.gov/d/2012-6586/p-amd-6>

⁴ <https://www.federalregister.gov/d/2012-6586/p-780>

2.1.2 NO_x Emissions History

Since the NO_x control technologies were installed on Unit 1 and Unit 2 in different years, the baseline emissions rate was determined using different time frames for Unit 1 and Unit 2. The time period from January 2015 through December 2018 was used to determine the NO_x baseline emissions rate for Unit 1. The time period from January 2017 through December 2018 was used to determine the NO_x baseline emissions rate for Unit 2. This information is displayed in Table 3.

Table 3: NO_x emissions

Year	Unit 1 Emissions		Unit 2 Emissions		Difference Between Units	
	lb NO _x /MMBtu	tons NO _x	lb NO _x /MMBtu	tons NO _x	lb NO _x /MMBtu	tons NO _x
2014 ^A	0.20	3,196	0.32	6,052	0.12	2,856
2015	0.11	2,103	0.36	7,283	0.25	5,180
2016 ^B	0.13	2,358	0.19	2,683	0.06	325
2017	0.11	1,662	0.11	2,045	0.00	383
2018	0.10	1,783	0.10	1,806	0.00	23
Baseline	0.11	1,723	0.11	1,926	0.01	203

^A SOFA/LNCFS began operation on Unit 1 in May 2014

^B SOFA/LNCFS began operation on Unit 2 in July 2016

The average emissions rate of 0.11 lb NO_x per MMBtu is representative of future expected operations. This value is used as the starting point when determining the cost of compliance for the add-on controls evaluated in Section 3.2.

2.2 SO₂

2.2.1 SO₂ Emissions Controls

AVS is equipped with dry flue gas desulfurization (DFGD) and a fabric filter (FF) baghouse for SO₂ and particulate matter control. The DFGD and FF baghouse were installed during the construction of the facility and have not been significantly modified since. AVS was not required to install any additional SO₂ controls during the first round of the regional haze program.⁵

2.2.2 SO₂ Emissions History

The time period from January 2014 through December 2018 was used to determine the SO₂ baseline emissions rate from AVS. This information is displayed in Table 4.

Table 4: SO₂ emissions

Year	Unit 1 Emissions		Unit 2 Emissions		Difference Between Units	
	lb SO ₂ /MMBtu	tons SO ₂	lb SO ₂ /MMBtu	tons SO ₂	lb SO ₂ /MMBtu	tons SO ₂
2014	0.38	5,809	0.38	6,975	0.00	1,166
2015	0.34	6,312	0.34	6,716	0.00	404
2016	0.39	7,254	0.34	5,089	0.05	2,165
2017	0.35	5,259	0.41	7,603	0.06	2,344
2018	0.35	5,911	0.35	6,126	0.00	215

⁵ <https://www.federalregister.gov/d/2012-6586/p-127>

Year	Unit 1 Emissions		Unit 2 Emissions		Difference Between Units	
	lb SO ₂ /MMBtu	tons SO ₂	lb SO ₂ /MMBtu	tons SO ₂	lb SO ₂ /MMBtu	tons SO ₂
Baseline	0.36	6,109	0.36	6,502	0.00	393

The average emissions rate of 0.36 lb SO₂ per MMBtu is representative of future expected operations. This value is used as the starting point when determining the cost of compliance for the add-on controls evaluated in Section 4.2.

3 NO_x Analysis

3.1 NO_x Technologies

Rich reagent injection (RRI), gas reburn, and innovative technologies such as NO_xStarTM, PerNO_xide, LoTO_x, and water injection were evaluated in Basin's four-factors analysis but were determined to not be available or technically feasible.⁶

RRI is a technology created for cyclone boilers. Unit 1 and Unit 2 at AVS are tangentially fired coal boilers. Therefore, RRI is considered to not be technically feasible.

Gas reburn would require extensive testing at both Unit 1 and Unit 2. Therefore, gas reburn is considered to not be technically feasible.

NO_xStarTM is currently an emerging technology and long-term full-scale demonstration testing would be required to demonstrate its effectiveness at AVS. PerNO_xide has only been tested on a pilot-scale and has not yet been demonstrated on any coal-fired boilers. Although LoTO_x has been successfully applied in refinery applications, there are not currently any full-scale installations on coal-fired boilers. The injection of atomized water spray to lower NO_x production has been well demonstrated for combustion turbine applications but has not been sufficiently demonstrated in coal-fired applications. Therefore, further testing is required for each of these innovative technologies to demonstrate that any of them could be installed effectively at AVS. They are considered to not be technically feasible at this time.

The reasonable progress controls evaluated by AVS and determined to be available and technically feasible are listed in Table 5. Note that the expected annual emissions in Table 5 were calculated using the performance rate, potential heat input, and the ACF (Table 2). Therefore, the tons of NO_x emissions are different than the tons of NO_x emissions displayed in Table 3 since Table 5 contains calculated emissions based on representative operations.

Table 5: Reasonable Progress NO_x Controls

Control Technology	Control Technology Abbreviation	Performance Rate (lb NO _x /MMBtu)	Emissions (tons/year)
Separated Overfire Air with Low-NO _x Concentric Firing System (baseline)	SOFA/LNCFS	0.11	1,917
Selective Non-Catalytic Reduction	SNCR	0.09	1,568
Selective Catalytic Reduction - Tail End Configuration	TE-SCR	0.05	871

⁶ Appendix B.2.b, p. 5-17. PDF page 312.

3.1.1 Selective Non-Catalytic Reduction (SNCR)

Installation of SNCR post combustion add-on control equipment has a limited impact on removing NO_x emissions from the flue gas. The limited removal is due to low NO_x concentrations in the flue gas stream affecting the reaction kinetics.⁷ Sources that are well suited for SNCR typically have an uncontrolled NO_x concentration above 200 ppm.⁸ AVS is generally around 60 ppm uncontrolled NO_x, making AVS not well suited for SNCR application. SNCR is anticipated to provide an approximately 18% reduction in NO_x emissions from the baseline scenario, lowering the expected performance rate from 0.11 to 0.09 lb NO_x per MMBtu. SNCR has a limited impact on reducing NO_x, however, installation of SNCR on Unit 1 and Unit 2 at AVS is technically feasible and will be evaluated further.

3.1.2 Selective Catalytic Reduction (SCR)

SCR is post combustion add-on control equipment. SCR, when feasible, has a significant impact on removing NO_x emissions from a flue gas stream. SCR is traditionally installed in one of three configurations: high-dust, low-dust, or tail-end. During the first regional haze program planning period in North Dakota, the Department determined that installation of SCR, in any configuration, is not a technically feasible control technology since it has not been demonstrated in practice on North Dakota lignite coal.⁹ However, the earlier determination focused on cyclone-fired boilers. Successful use of TE-SCR controls have since been demonstrated at existing bituminous- and subbituminous-fired units. Therefore, the current determination is deeming TE-SCR as being technically feasible. TE-SCR is anticipated to provide an approximately 55% reduction in NO_x emissions from the baseline scenario, lowering the expected performance rate from 0.11 to 0.05 lb NO_x per MMBtu. TE-SCR is assumed technically feasible for installation on Unit 1 and Unit 2 at AVS and will be evaluated further.

3.2 Step 1 – Cost of Compliance

The cost of compliance and incremental cost for the reasonable progress controls are listed in Table 6.

Table 6: NO_x Cost of Compliance and Incremental Cost of Compliance

Control Technology	Performance Rate (lb/MMBtu)	Annual Emission Reduction (tpy)	Annualized Total Cost (\$)	Cost of Compliance (\$/ton)	Incremental Cost of Compliance (\$/ton)
SOFA/LNCFS (Baseline)	0.11				
SNCR	0.09	349	3,285,412	9,426	
TE-SCR	0.05	1,046	36,344,908	34,758	47,424

A detailed breakdown of the costs listed in Table 6 can be found in Basin's submitted four factors analysis.¹⁰ The Department has reviewed these costs and believes them to be accurate.

⁷ John Sorrels, EPA Cost control Manual, Section 4, Chapter 1, p 1-16.

⁸ John Sorrels, EPA Cost control Manual, Section 4, Chapter 1, p 1-5.

⁹ North Dakota State Implementation Plan for Regional Haze, March 3, 2010, Appendix B.5.

¹⁰ Appendix B.2.b. Appendix D. PDF page 356.

If SNCR is installed, a performance rate improvement of 0.02 lb NO_x per MMBtu could be achieved. This equates to a potential reduction of 349 tons NO_x per year from the baseline emissions. Fiscally, SNCR installation requires an estimated annualized cost of \$3.3 million and a NO_x removal cost of \$9,400 per ton.

If TE-SCR is installed, a performance rate improvement of 0.06 lb NO_x per MMBtu could be achieved. This equates to a potential reduction of 1,046 tons NO_x per year from the baseline emissions. Fiscally, TE-SCR installation requires an estimated annualized cost of \$36.3 million and a NO_x removal cost of approximately \$35,000 per ton.

3.3 Step 2 – Time Necessary for Compliance

A summary of the anticipated timelines for the installation of SNCR and TE-SCR is provided in Table 7.

Table 7: Time Required for NO_x Controls

Control Technology	Total time after SIP approval (months)
SNCR	22
TE-SCR	52

The anticipated timelines for the installation of SNCR and TE-SCR indicate either option could be installed prior to the end of the second planning period.

3.4 Step 3 – Energy and Non-Air Quality Environmental Impacts

3.4.1 Energy

The installation and operation of a TE-SCR would increase the pressure drop through the control systems, which would increase the auxiliary power requirements. This would adversely affect the net plant heat rate. This impact is significant but not significant enough to eliminate TE-SCR as a control option.

3.4.2 Non-Air Quality Environmental Impacts

The installation and operation of the TE-SCR could result in an increase in sulfur emissions due to the potential oxidation of SO₂ to SO₃ and the subsequent reaction with moisture in the stack to form H₂SO₄.

Both TE-SCR and SNCR use ammonia as a reagent. Ammonia slip emissions will result in the flue gas stream on the exhaust side of the control equipment due to the the operation of TE-SCR (~2 ppm) and SNCR (~10 ppm). The ammonia slip emissions from the operation of SNCR would likely combine with the dry FGD solids. The ammoniated dry FGD solids would require that further safety precautions are taken for AVS staff who perform maintenance on the ash handling system or staff who dispose of waste. Ammonia slip emissions from the operation of the TE-SCR would be emitted to the atmosphere. Subsequently, the ammonia could combine with SO_x and NO_x to form sulfates and nitrates, which will affect visibility.

The non-air quality environmental impacts for TE-SCR and SNCR are significant but not significant enough to eliminate either of them as a control option.

3.5 Step 4 – Remaining Useful Life

Based on the information provided to the Department, AVS is expected to operate beyond the life of the control equipment. Therefore, remaining useful life was not considered.

4 SO₂ Analysis

4.1 SO₂ Technologies

Fuel switching was evaluated in Basin's four-factors analysis but was not determined to be available since AVS is a mine mouth generation facility.

The reasonable progress controls evaluated by AVS are listed in Table 8. Performance rate and expected annual emissions are included for each control technology that was determined to be technically feasible. Note that the expected annual emissions in Table 8 were calculated using the performance rate, potential heat input, and the ACF (Table 2). Therefore, the tons of SO₂ emissions are different than the tons of SO₂ emissions displayed in Table 4 since Table 8 contains calculated emissions based on representative operations.

Table 8: Reasonable Progress SO₂ Controls

Control Technology	Control Technology Abbreviation	Performance Rate (lb SO ₂ /MMBtu)	Emissions (tons/year)
Dry Flue Gas Desulfurization / Fabric Filter (baseline)	DFGD/FF	0.36	6,274
Existing DFGD Operational Improvement: Station Work Practice	Station Work Practice	0.35	6,100
Existing DFGD Operational Improvement: Increase Ca:S Stoichiometric Ratio ^A	Ca:S Stoichiometry	0.20	3,486
New Retrofit DFGD (Circulating Dry Scrubber / Fabric Filter)	DFGD (CDS/FF)	0.09	1,568
New Retrofit Wet Flue Gas Desulfurization	WFGD	0.07	1,220

^A Dry sorbent injection was also considered but would not provide any additional SO₂ removal beyond what can be achieved by increasing the Ca:S stoichiometric ratio.

4.1.1 Flue Gas Desulfurization (FGD) Improvements

FGD Improvements are grouped into two categories: 1) equipment upgrades and 2) operational improvements. The proposed equipment upgrades consisted of atomizer replacement, lime-slaker replacement, adding an absorber module, and replacing the existing absorber module. The proposed operational improvements evaluated consisted of station work practices, increasing the lime quality, increasing the stoichiometric ratio of calcium to sulfur (Ca:S) by increasing lime quantity, and lowering the absorber outlet temperature closer to the saturation point.

None of the equipment upgrades are considered technically feasible.¹¹ It is not technically feasible to replace the atomizer in order to improve air pollution control because there has not been any significant moisture carry-over into the baghouse or wetting of the absorber walls that would indicate

¹¹ Appendix B.2.b, p 4-20. PDF page 284.

that the atomizers are not operating properly. Since additional slaking capacity was installed in 2011, it is not technically feasible to replace the slakers in order to reduce emissions. In addition, an additional absorber module or the replacement of any existing absorber modules would not provide any significant improvements towards removing additional sulfur. Therefore, adding an absorber module or replacing any existing absorber modules are considered to not be technically feasible SO₂ control strategies.

When considering the potential operational improvements, increasing the lime quality and lowering the absorber outlet temperature closer to the saturation point are not considered technically feasible. The lime used at AVS is already of high quality for use in dry scrubbers. Therefore, it is not technically feasible to increase the quality of the lime to reduce SO₂ emissions. Similarly, it is not technically feasible to further lower the outlet temperature closer to the saturation point because the AVS dry scrubbers currently operate at a temperature near the adiabatic saturation temperature. Station work practices and increasing the stoichiometric ratio of Ca:S are both considered technically feasible.

The initiation of certain “station work practices” has the ability to decrease SO₂ emissions at AVS. Unit 1 and Unit 2 at AVS have a combined 3-hour rolling average SO₂ limit of 3,845 lb/hr in their Title V Permit to Operate (T5-F86003).¹² When either Unit 1 or Unit 2 is in an extended major outage, operators decrease the SO₂ removal on the other Unit, while maintaining compliance with the SO₂ permit limit. This typically occurs once every three years on each unit. Station work practices are anticipated to provide an approximately 3% reduction in SO₂ emissions from the baseline scenario, lowering the expected performance rate from 0.36 lb SO₂ per MMBtu to 0.35 lb SO₂ per MMBtu. A change to the current station work practices is considered a technically feasible SO₂ control option for AVS Unit 1 and Unit 2.

For AVS, increasing the Ca:S stoichiometric ratio is best accomplished by increasing the quantity of fresh lime introduced into the system. Basin contracted with Babcock and Wilcox (B&W), the original equipment manufacturer of AVS’s DFGD system, to determine whether additional SO₂ could be removed if the amount of fresh lime added to the system was increased. Based on simulations conducted by B&W’s proprietary software, AVS could achieve a performance rate of 0.16 lb SO₂ per MMBtu by increasing the amount of fresh lime added to the system. This equates to a 44% reduction in SO₂ emissions from the baseline scenario of 0.36 lb SO₂ per MMBtu. Increasing the Ca:S stoichiometric ratio is considered a technically feasible SO₂ control option for AVS Unit 1 and Unit 2.

4.1.2 New Dry FGD (DFGD) and Fabric Filter (FF)

Two types of new DFGD systems were evaluated at AVS: 1) a spray dryer absorber (SDA) and 2) a circulating dry scrubber (CDS). Each of these systems is technically feasible, commercially available, and would require significant modifications to the facility. The engineering evaluation determined that the CDS would outperform the SDA at AVS.¹³ A new SDA/FF is anticipated to be able to achieve a performance rate of 0.15 lb SO₂ per MMBtu. A new CDS/FF is anticipated to be able to achieve a performance rate of 0.09 lb SO₂ per MMBtu. Given the better performance rate with the CDS/FF system, the Department will focus the remaining analysis on the CDS/FF system. Implementation of a CDS/FF system represents a 75% reduction from the baseline scenario of 0.36 lb SO₂ per MMBtu.

¹² Appendix B.2.c. PDF page 373.

¹³ Appendix B.2.b, p 4-17. PDF page 281.

Replacing the existing DFGD unit with a new CDS/FF is technically feasible and will be evaluated further.

4.1.3 Wet FGD (WFGD)

Replacing the DFGD with a WFGD system located downstream of the existing FF was the most effective and most costly SO₂ control option evaluated. WFGD systems are well established and are operated on many coal-fired power plants that fire medium- to high-sulfur coal. All WFGD systems use an alkaline slurry that reacts with SO₂ to form calcium sulfite and calcium sulfate. A WFGD system designed for AVS is anticipated to be able to achieve a performance rate of 0.07 lb SO₂ per MMBtu, or an 81% reduction from the baseline emissions scenario of 0.36 lb SO₂ per MMBtu. Installation of a new WFGD system is technically feasible and will be evaluated further.

4.2 Step 1 – Cost of Compliance

The cost of compliance and incremental cost of compliance for the reasonable progress controls are listed in Table 9.

Table 9: SO₂ Cost of Compliance and Incremental Cost of Compliance

Control Technology	Performance Rate (lb SO₂/MMBtu)	Annual Emission Reduction (tpy)	Annualized Total Cost (\$)	Cost of Compliance (\$/ton)	Incremental Cost of Compliance (\$/ton)
DFGD/FF (Baseline)	0.36				
Station Work Practice	0.35	174	135,000	775	
Ca:S Stoichiometry	0.20	2,788	1,938,773	695	690
DFGD (CDS/FF)	0.09	4,705	35,603,658	7,566	17,561
WFGD	0.07	5,054	39,267,491	7,770	10,512

A detailed breakdown of the costs listed in Table 9 can be found in Basin's submitted four factors analysis.¹⁴ The Department has reviewed these costs and believes them to be accurate.

There are many options available for AVS to reduce SO₂ emissions. The control costs vary drastically in annualized cost and significantly in effectiveness. A summary of each option evaluated is provided in the following paragraphs.

A change to the current station work practices would provide a potential 3% reduction in emissions from the baseline scenario. This would result in approximately 170 tons of SO₂ being reduced at an annualized cost of approximately \$135,000, equating to \$775 per ton of SO₂ reduced. As stated in Section 4.3, a change to the current station work practices can be implemented very quickly, which would provide for a quick reduction in SO₂ emissions from the facility.

¹⁴ Appendix B.2.b. Appendix C. PDF page 343.

FGD Improvements, specifically Ca:S stoichiometric adjustments, provide a potential 44% reduction in emissions from the baseline scenario. This would result in approximately 2,790 tons of SO₂ being reduced at an annualized cost of approximately \$1.9 million, equating to approximately \$700 per ton of SO₂ reduced. A benefit of this control option is that the facility can take advantage of upgrading existing equipment at a low capital cost when compared to replacement with new equipment at a high capital cost.

Replacing the existing DFGD unit and FF with a new CDS/FF unit would provide for a 75% reduction in emissions from the baseline scenario. This would result in approximately 4,700 tons of SO₂ being reduced at an annualized cost of \$35.6 million, equating to approximately \$7,600 per ton of SO₂ reduced.

Replacing the existing DFGD unit with a new WFGD unit would provide for an 81% reduction in emissions from the baseline scenario. This would result in approximately 5,050 tons of SO₂ reduced at an annualized cost of \$39.3 million, equating to approximately \$7,800 per ton of SO₂ reduced.

4.3 Step 2 – Time Necessary for Compliance

A summary of the anticipated timelines for the installation of the technically feasible control technologies is provided in Table 10.

Table 10: Time Required for SO₂ Controls

Control Technology	Total time after SIP approval (months)
Station Work Practice	3
Ca:S Stoichiometry	51
DFGD (CDS/FF)	56
WFGD	60

The anticipated timelines for the installation of each of the control technologies indicates all options could be installed prior to the end of the second planning period.

4.4 Step 3 – Energy and Non-Air Quality Environmental Impacts

4.4.1 Energy

The replacement of the existing drying scrubbing system with a CDS/FF or WFGD would increase the pressure drop through the control systems, which will increase the auxiliary power requirements. This would adversely affect the net plant heat rate. This impact is significant but not significant enough to eliminate either CDS/FF or WFGD as a control option.

4.4.2 Non-Air Quality Environmental Impacts

The installation and operation of a WFGD control option would generate a liquid calcium sulfate by-product that would need to be dewatered prior to disposal. In addition, WFGD control systems generate wastewater streams that typically contain a saturated solution of calcium sulfate, calcium sulfite, sodium chloride, trace amounts of fly ash, and unreacted limestone. The wastewater stream would need to be treated prior to discharge. WFGD systems also require significantly more water than dry systems. The non-air quality environmental impacts for WFGD are significant but not significant enough to eliminate WFGD as a control option.

4.5 Step 4 – Remaining Useful Life

Based on the information provided to the Department, AVS is expected to operate beyond the life of the control equipment. Therefore, remaining useful life was not considered.

A.3 – Basin LOS

1 Introduction and Representative Operations

Basin Electric Power Cooperative (Basin) – Leland Olds Station (LOS) is a two-unit electrical generating station. Unit 1 and Unit 2 both primarily fire lignite with a small amount of subbituminous coal combusted. Unit 1 began commercial operation in 1966 and is a Babcock & Wilcox opposed wall-fired boiler that has the capacity to produce approximately 216 Megawatts (MW) per hour of electricity. Unit 2 began commercial operation in 1975 and is a Babcock & Wilcox cyclone-fired boiler that has the capacity to produce approximately 440 MW per hour of electricity. LOS is located on the banks of the Missouri River in eastern Mercer county, approximately four miles southeast of the town of Stanton, North Dakota. LOS receives lignite from the Coteau Properties Freedom Mine, which is located approximately thirty miles west of LOS.

The average annual amount of coal combusted at LOS from 2009 through 2018 was approximately 1 million tons for Unit 1 and 2 million tons for Unit 2. See Table 1 for detailed information.

Table 1: Yearly Coal Combusted (tons)

Year	Unit 1	Unit 2
2009	1,287,756	2,125,157
2010	1,163,282	2,081,633
2011	877,802	1,821,590
2012	1,013,575	1,826,247
2013	1,114,170	2,373,552
2014	888,389	2,151,508
2015	1,172,715	1,872,825
2016	1,164,055	2,266,471
2017	944,117	2,270,661
2018	1,104,951	1,797,457
Average	1,073,081	2,058,710

Over the same 10-year period (2009–2018), LOS operated at a 62% annual capacity factor (ACF) for Unit 1 and 60% ACF for Unit 2, as determined on an actual heat input basis. Based on information provided to the North Dakota Department of Environmental Quality, Division of Air Quality (Department), future operations are expected to be consistent with this 10-year period. The 62% and 60% annual capacity factors were used when calculating the baseline and future projected emissions discussed in Section 2.

Table 2 and Table 3 display the operational information from 2009–2018 for LOS Unit 1 and Unit 2, respectively. The ACF is calculated by dividing the actual heat input by the maximum potential heat input of each unit. The maximum potential heat input of Unit 1 is 23.0×10^6 MMBtu per year and the maximum potential heat input of Unit 2 is 44.9×10^6 MMBtu per year.

Table 2: Unit 1 Utilization and Annual Capacity Factor

Year	Unit 1 Heat Input MMBtu/yr	Unit 1 Annual Capacity Factor
2009	17,175,940	0.75

Year	Unit 1 Heat Input MMBtu/yr	Unit 1 Annual Capacity Factor
2010	15,297,310	0.67
2011	11,653,716	0.51
2012	13,716,670	0.60
2013	14,639,199	0.64
2014	11,933,747	0.52
2015	15,787,030	0.69
2016	15,566,955	0.68
2017	12,515,725	0.54
2018	14,285,928	0.62
Average	14,257,222	0.62

Table 3: Unit 2 Utilization and Annual Capacity Factor

Year	Unit 2 Heat Input MMBtu/yr	Unit 2 Annual Capacity Factor
2009	27,865,279	0.62
2010	26,903,299	0.60
2011	23,660,990	0.53
2012	23,477,374	0.52
2013	30,526,164	0.68
2014	28,352,132	0.63
2015	24,730,648	0.55
2016	30,344,385	0.68
2017	29,914,155	0.67
2018	23,585,131	0.52
Average	26,935,956	0.60

2 NO_x and SO₂ Emissions Controls and History

LOS commenced operation in 1966 when Unit 1 was started up. As is stated above, Unit 2 was started up in 1975. LOS was a best available retrofit technology (BART) eligible source since construction of the facility commenced before the August 7, 1977 end date for “facilities in existence” and after August 7, 1962. The Department determined that BART for LOS Unit 1 and Unit 2 included new wet limestone flue gas desulfurization (WFGD) for SO₂ control and selective non-catalytic reduction (SNCR) and separated overfire (SOFA) air for NO_x control.¹

LOS was also subject to the reasonable progress requirements during the first round of the Regional Haze program. The Department determined that no additional NO_x or SO₂ controls were required for LOS Unit 1 or Unit 2 within the reasonable progress requirements.²

¹ North Dakota State Implementation Plan for Regional Haze, Appendix B.1.

² North Dakota State Implementation Plan for Regional Haze, March 3, 2010, p. 188.

The United States Environmental Protection Agency (EPA) proposed to partially approve and partially disapprove of North Dakota's State Implementation Plan for Regional Haze submitted on March 3, 2010. In regard to LOS, the EPA proposed to disapprove the NO_x BART determination and emissions limit for Unit 2.³ The EPA proposed the promulgation of a Federal Implementation Plan (FIP), which proposed advanced separated overfire air (ASOFA) plus selective catalytic reduction (SCR) and an emission rate of 0.07 lb/MMBtu (30-day rolling average) as BART for NO_x control on LOS Unit 2.⁴ Following the public notice and comment period, the EPA issued its Final Rule on April 6, 2012.⁵ In the Final Rule, EPA reversed its position regarding the technical feasibility of SCR on LOS Unit 2 and approved North Dakota's BART determination for NO_x control on Unit 2.⁶ Therefore, a FIP was not promulgated for NO_x BART on LOS Unit 2 and the Department's initial BART determination for both LOS Unit 1 and Unit 2 was approved.

2.1 NO_x

2.1.1 NO_x Emissions Controls

The NO_x air pollution control system upgrades including SOFA and SNCR for Unit 1 and Unit 2 were placed into service in stages over several years. The final stages included the startup of SNCR on Unit 1 and Unit 2 in August 2015. Optimization of the NO_x air pollution control system upgrades were needed through 2015. The SNCR on Unit 1 and Unit 2 were again optimized in 2017, lowering the NO_x emissions rate. The current NO_x air pollution control system operating on Unit 1 and Unit 2 includes SOFA and SNCR.

2.1.2 NO_x Emissions History

The baseline emissions rate for NO_x was determined using the time period of January 2017 through December 2018 for both Unit 1 and Unit 2. This information is displayed in Table 4 and Table 5.

Table 4: Unit 1 Annual NO_x Rate and Emissions

Year	Emissions Rate (lb/MMBtu)	NO_x Emissions (tons)
2014	0.22	1,373
2015 ^A	0.24	1,814
2016	0.25	1,856
2017 ^B	0.18	1,121
2018	0.15	1,065
Baseline	0.16	1,093

^A SNCR began operation in August 2015

^B SNCR was reoptimized in 2017

³ <https://www.federalregister.gov/d/2011-23372/p-253>.

⁴ <https://www.federalregister.gov/d/2011-23372/p-705>.

⁵ <https://www.federalregister.gov/d/2012-6586/p-3>.

⁶ <https://www.federalregister.gov/d/2012-6586/p-159>.

Table 5: Unit 2 Annual NO_x Rate and Emissions

Year	Emissions Rate (lb/MMBtu)	NO _x Emissions (tons)
2014	0.37	5,202
2015 ^A	0.37	4,557
2016	0.37	5,434
2017 ^B	0.29	4,418
2018	0.29	3,599
Baseline	0.29	4,009

^A SNCR began operation in August 2015

^B SNCR was reoptimized in 2017

Unit 1 and Unit 2 contain different boiler types and are not expected to operate in similar ways. Table 4 and Table 5 show that Unit 1 and Unit 2 are not comparable in terms of emissions rate or emissions. Therefore, each unit has its own value for baseline emissions rate. The average emissions rate of 0.16 lb NO_x per MMBtu is representative of future expected operations for Unit 1. The average emissions rate of 0.29 lb NO_x per MMBtu is representative of future expected operations for Unit 2. These values are used as the starting point when determining the cost of compliance for the add-on controls evaluated in Section 3.2.

2.2 SO₂

2.2.1 SO₂ Emissions Controls

The new WFGD for SO₂ control was started up on Unit 1 in June 2013 and on Unit 2 in October 2012. The current SO₂ air pollution control system operating on Unit 1 and Unit 2 consists of WFGD, as required by BART.

2.2.2 SO₂ Emissions History

The time period from January 2015 through December 2018 was used to determine the SO₂ baseline emissions rate from Unit 1 and Unit 2 at LOS. This information is displayed in Table 6 and Table 7.

Table 6: Unit 1 Annual SO₂ Rate and Emissions

Year	Emissions Rate (lb/MMBtu)	SO ₂ Emissions (tons)
2014	0.06	412
2015	0.09	681
2016	0.09	711
2017	0.09	554
2018	0.09	652
Baseline	0.09	650

Table 7: Unit 2 Annual SO₂ Rate and Emissions

Year	Emissions Rate (lb/MMBtu)	SO ₂ Emissions (tons)
2014	0.07	1,025
2015	0.09	1,066
2016	0.08	1,217
2017	0.09	1,364
2018	0.08	1,052
Baseline	0.08	1,175

As displayed in Table 6 and Table 7, Unit 1 and Unit 2 are not comparable in terms of tons of SO₂ emitted since Unit 2 is approximately twice as large. However, the emission rates, in terms of lb SO₂ per MMBtu are comparable between Unit 1 and Unit 2, due to each unit operating a WFGD unit and firing similar coal.⁷ The average emissions rate of 0.09 lb SO₂ per MMBtu for Unit 1 is representative of future expected operations. The average emissions rate of 0.08 lb SO₂ per MMBtu for Unit 2 is representative of future expected operations for Unit 2. These values are used as starting points when determining the cost of compliance for the add-on controls evaluated in Section 4.2.

3 NO_x Analysis

3.1 NO_x Technologies

Gas reburn and innovative technologies such as NO_xStarTM, PerNO_xide, LoTO_x, and water injection were evaluated in Basin's four-factors analysis but were determined to not be available or technically feasible.⁸

Gas reburn would require extensive testing at both Unit 1 and Unit 2. Therefore, gas reburn is considered to not be technically feasible.

NO_xStarTM is currently an emerging technology and long-term full-scale demonstration testing would be required to demonstrate its effectiveness at LOS. PerNO_xide has only been tested on a pilot-scale and has not yet been demonstrated on any coal-fired boilers. Although LoTO_x has been successfully applied in refinery applications, there are not currently any full-scale installations on coal-fired boilers. The injection of atomized water spray to lower NO_x production has been well demonstrated for combustion turbine applications but has not been sufficiently demonstrated in coal-fired applications. Therefore, further testing is required for each of these innovative technologies to demonstrate that any of them could be installed effectively at LOS. They are considered to not be technically feasible at this time for either Unit 1 or Unit 2.

The reasonable progress controls evaluated by LOS determined to be available and technically feasible are listed in Table 8 (Unit 1) and Table 9 (Unit 2). Performance rate and expected annual emissions are included for each control technology determined to be technically feasible. Note that the expected annual emissions in Table 8 and Table 9 were calculated using the performance rate, potential heat input, and the ACF (Table 2 and Table 3). Therefore, the tons of NO_x emissions are

⁷ When rounded to three decimal places, Unit 1 average is 0.088 and Unit 2 average is 0.084.

⁸ Appendix B.3.b, p. 5-18 – 5-20. PDF page 448-450.

different than the tons of NO_x emissions displayed in Table 4 and Table 5 since the tables below contain calculated emissions based on representative operations.

Table 8: Reasonable Progress NO_x Controls (Unit 1)

Control Technology	Control Technology Abbreviation	Performance Rate (lb NO_x/MMBtu)	Emissions (tons/year)
Low-NO _x Burner with Selective Non-Catalytic Reduction and Separated Overfire Air (baseline)	LNB/SNCR/SOFA	0.16	1,152
Selective Catalytic Reduction - Tail End Configuration	TE-SCR	0.05	356

Table 9: Reasonable Progress NO_x Controls (Unit 2)

Control Technology	Control Technology Abbreviation	Performance Rate (lb NO_x/MMBtu)	Emissions (tons/year)
Selective Non-Catalytic Reduction with Separated Overfire Air (baseline)	SNCR/SOFA	0.29	3,894
Optimized Selective Non-Catalytic Reduction	Optimized SNCR	0.27	3,636
Optimized Selective Non-Catalytic Reduction with Rich Reagent Injection	Optimized SNCR + RRI	0.22	2,963

3.1.1 Optimized Selective Non-Catalytic Reduction (SNCR)

SNCR is currently installed on Unit 1 and Unit 2 at LOS, as required by the first round of Regional Haze planning for North Dakota. Therefore, optimization of SNCR is being considered as an option to reduce NO_x emissions.

Based on computational fluid dynamics modeling conducted for Unit 1 at LOS, any additional urea injection could result in negative impacts with ammonia slip emissions. In addition, during installation of the SNCR control equipment on Unit 1, it was determined that it would not be possible to install any multi-nozzle lances in their optimal locations due to physical interferences. Therefore, the current SNCR system on Unit 1 is considered fully optimized.

Optimization of the SNCR control equipment on Unit 2 is considered technically feasible. The SNCR original equipment manufacturer proposed that the SNCR system on Unit 2 could be further optimized by relocating all cyclone vent ports to improve stoichiometry and relocating the current urea injection lances to better utilize the reagent. Optimization of the SNCR control equipment is anticipated to provide an approximately 7% reduction in NO_x emissions from the baseline scenario. This would lower the expected performance rate from 0.29 to 0.27 lb NO_x per MMBtu. Optimization of SNCR is assumed to be technically feasible for installation on Unit 2 at LOS and will be evaluated further.

3.1.2 Selective Catalytic Reduction (SCR)

SCR is post combustion add-on control equipment. SCR, when feasible, can have a significant impact on removing NO_x emissions from a flue gas stream. SCR is traditionally installed in one of three configurations: high-dust, low-dust, or tail-end. During the first regional haze program planning period

in North Dakota, the Department determined that installation of SCR, in any configuration, is not a technically feasible control technology since it has not been demonstrated in practice on North Dakota lignite.⁹

The earlier determination focused on North Dakota lignite-fired cyclone boilers. Therefore, SCR is not considered technically feasible for Unit 2 at LOS.

Successful use of TE-SCR controls has since been demonstrated at existing bituminous- and subbituminous-fired units. Even though this has not been demonstrated on North Dakota lignite-fired boilers, the current determination is deeming TE-SCR as being technically feasible for Unit 1 at LOS, which is an opposed wall-fired boiler. TE-SCR is anticipated to provide an approximately 69% reduction in NO_x emissions from the baseline scenario on Unit 1. This would lower the expected performance rate from 0.16 to 0.05 lb NO_x per MMBtu for Unit 1. TE-SCR is assumed to be technically feasible for installation on Unit 1 at LOS and will be evaluated further.

3.1.3 Optimized Selective Non-Catalytic Reduction (SNCR) Plus Rich Reagent Injection (RRI)

Rich reagent injection (RRI) is a technology created for cyclone boilers. Therefore, RRI is not considered to be a technically feasible option for Unit 1.

RRI alone only provides a beneficial NO_x reduction at full load. However, if RRI is coupled with SNCR, NO_x reduction can be achieved through a wider range of operating loads on Unit 2. Optimized SNCR + RRI is anticipated to provide an approximately 24% reduction in NO_x emissions from the baseline scenario on Unit 2. This would lower the expected performance rate from 0.29 to 0.22 lb NO_x per MMBtu for Unit 2. Optimized SNCR + RRI is assumed to be technically feasible for installation on Unit 2 at LOS and will be evaluated further.

3.2 Step 1 – Cost of Compliance

The cost of compliance and incremental cost for the reasonable progress controls are listed in Table 10 (Unit 1) and Table 11 (Unit 2).

Table 10: NO_x Cost of Compliance and Incremental Cost of Compliance (Unit 1)

Control Technology	Performance Rate (lb/MMBtu)	Annual Emission Reduction (tpy)	Annualized Total Cost (\$)	Cost of Compliance (\$/ton)
LNB/SNCR/SOFA (Baseline)	0.16			
TE-SCR	0.05	796	33,663,928	42,316

⁹ North Dakota State Implementation Plan for Regional Haze, March 3, 2010, Appendix B.5.

Table 11: NO_x Cost of Compliance and Incremental Cost of Compliance (Unit 2)

Control Technology	Performance Rate (lb/MMBtu)	Annual Emission Reduction (tpy)	Annualized Total Cost (\$)	Cost of Compliance (\$/ton)	Incremental Cost of Compliance (\$/ton)
SNCR/SOFA (Baseline)	0.29				
Optimized SNCR	0.27	258	924,151	3,582	
Optimized SNCR + RRI	0.22	931	5,402,503	5,801	6,650

A detailed breakdown of the costs listed in Table 10 and Table 11 can be found in Basin's submitted four factors analysis.¹⁰ The Department has reviewed these costs and believes them to be accurate.

If TE-SCR is installed on Unit 1, a performance rate improvement of 0.09 lb NO_x per MMBtu could be achieved. This equates to a potential reduction of approximately 800 tons NO_x per year from the baseline emissions. Fiscally, TE-SCR installation requires an estimated annualized cost of \$33.6 million and a NO_x removal cost of approximately \$42,000 per ton.

If SNCR is optimized on Unit 2, a performance rate improvement of 0.02 lb NO_x per MMBtu could be achieved. This equates to a potential reduction of approximately 260 tons NO_x per year from the baseline emissions. Fiscally, SNCR optimization on Unit 2 requires an estimated annualized cost of approximately \$924,000 and a NO_x removal cost of \$3,600 per ton.

If SNCR is optimized with RRI on Unit 2, a performance rate improvement of 0.07 lb NO_x per MMBtu could be achieved. This equates to a potential reduction of approximately 930 tons NO_x per year from the baseline emissions. Fiscally, SNCR optimization with RRI requires an estimated annualized cost of \$5.4 million and a NO_x removal cost of \$5,800 per ton.

3.3 Step 2 – Time Necessary for Compliance

A summary of the anticipated timeline for the installation of TE-SCR on Unit 1 is provided in Table 12.

Table 12: Time Required for NO_x Controls (Unit 1)

Control Technology	Total time after SIP approval (months)
TE-SCR	52

The anticipated timeline for the installation of TE-SCR on Unit 1 indicates that TE-SCR could be installed prior to the end of the second planning period.

A summary of the anticipated timelines for the optimization of SNCR and the optimization of SNCR plus RRI for Unit 2 is provided in Table 13.

¹⁰ Appendix B.3.b. Appendix D. PDF page 493

Table 13: Time Required for NO_x Controls (Unit 2)

Control Technology	Total time after SIP approval (months)
Optimized SNCR	12
Optimized SNCR + RRI	16

The anticipated timelines for the optimization of SNCR and the optimization of SNCR plus RRI indicate either option could be installed prior to the end of the second planning period.

3.4 Step 3 – Energy and Non-Air Quality Environmental Impacts

3.4.1 Energy

The installation and operation of a TE-SCR on Unit 1 would increase the pressure drop through the control systems, which would increase the auxiliary power requirements. This would adversely affect the net plant heat rate. This impact is significant but not significant enough to eliminate TE-SCR as a control option.

Optimization of the SNCR and optimization of the SNCR plus RRI on Unit 2 will adversely affect the net plant heat rate due to the amount of water that will be injected with urea, which will negatively impact boiler efficiency. This impact is significant but not significant enough to eliminate optimization of the SNCR or optimization of the SNCR plus RRI as control options.

3.4.2 Non-Air Quality Environmental Impacts

The installation and operation of the TE-SCR on Unit 1 could result in an increase in sulfur emissions due to the potential oxidation of SO₂ to SO₃ and the subsequent reaction with moisture in the stack to form H₂SO₄. In addition, TE-SCR uses ammonia as a reagent. Ammonia slip emissions will result in the flue gas stream on the exhaust side of the control equipment due to the operation of TE-SCR (~2 ppm). Ammonia slip emissions from the operation of the TE-SCR would be emitted to the atmosphere. The non-air quality environmental impacts for TE-SCR are significant but not significant enough to eliminate either of them as a control option.

3.5 Step 4 – Remaining Useful Life

Based on the information provided to the Department, LOS is expected to operate beyond the life of the control equipment. Therefore, remaining useful life was not considered.

4 SO₂ Analysis

4.1 SO₂ Technologies

As part of the first planning period for Regional Haze, LOS was required to install WFGD for SO₂ control on Unit 1 and Unit 2 at LOS. Therefore, improvements or upgrades to the existing WFGD systems are now considered for reasonable progress control options. The reasonable progress controls evaluated by LOS are listed in Table 14 (Unit 1) and Table 15 (Unit 2). Performance rate and expected annual emissions are included for each control technology that was determined to be technically feasible. Note that the expected annual emissions in Table 14 and Table 15 were calculated using the performance rate, potential heat input, and the ACF (Table 2 and Table 3). Therefore, the tons of SO₂ emissions are different than the tons of SO₂ emissions displayed in Table 6 and Table 7 since the tables below contain calculated emissions based on representative operations.

Table 14: Reasonable Progress SO₂ Controls (Unit 1)

Control Technology	Control Technology Abbreviation	Performance Rate (lb SO ₂ /MMBtu)	Emissions (tons/year)
Wet Limestone Flue Gas Desulfurization (baseline)	WFGD	0.088	630
Increase Ca:S Stoichiometric Ratio	Ca:S Stoichiometry	0.080	570
Incorporation of pH Buffer and Increasing Limestone Addition	pH Buffer Additive	0.055	392

Table 15: Reasonable Progress SO₂ Controls (Unit 2)

Control Technology	Control Technology Abbreviation	Performance Rate (lb SO ₂ /MMBtu)	Emissions (tons/year)
Wet Limestone Flue Gas Desulfurization (baseline)	WFGD	0.084	1138
Increase Ca:S Stoichiometric and Liquid-to-Gas Ratios	Ca:S Stoichiometry and L/G Ratio	0.075	1010
Incorporation of pH Buffer and Increasing Limestone Addition	pH Buffer Additive	0.050	673

Three decimal places are shown in Table 14 and Table 15 for the performance rate in order to properly illustrate the difference in performance rates between WFGD and Ca:S Stoichiometry.

4.1.1 Flue Gas Desulfurization (FGD) Improvements and Upgrades

FGD Improvements are grouped into two categories: 1) operational improvements and 2) design changes and equipment upgrades. The proposed operational improvements evaluated consisted of increasing the limestone quality, increasing the stoichiometric ratio of calcium to sulfur (Ca:S) by increasing limestone quantity, and improving the liquid-to-gas ratio. The proposed design changes and equipment upgrades consisted of adding an additional spray level, optimizing the spray level coverage, and the incorporation of a pH buffer.

When considering the potential operational improvements, increasing the quality of the limestone is not considered technically feasible for Unit 1 or Unit 2. The limestone used at LOS is already of high quality for use in wet scrubbers. Therefore, it is not technically feasible to increase the quality of the limestone to reduce SO₂ emissions.

Increasing the stoichiometric ratio of Ca:S is considered technically feasible. For LOS Unit 1 and Unit 2, increasing the Ca:S stoichiometric ratio is best accomplished by increasing the quantity of fresh limestone introduced into the system.

The limestone feed rate for Unit 1 is maintained near the maximum design stoichiometry based on the inlet SO₂ concentration. Therefore, increasing the fresh limestone addition rate slightly could provide minor additional SO₂ removal for Unit 1. Increasing the amount of fresh limestone added to the system would provide a performance rate improvement of 0.01 lb SO₂ per MMBtu. This equates

to a 10% reduction in SO₂ emissions from the baseline scenario of 0.09 lb SO₂ per MMBtu. Increasing the Ca:S stoichiometric ratio is considered a technically feasible SO₂ control option for LOS Unit 1.

The recycle slurry flow rates for Unit 1 indicate that Unit 1 operating pumps typically operate at their maximum capacity. The recycle pumps are not adjusted for operating load or SO₂ loading. Therefore, changes to the liquid-to-gas (L/G) ratio at Unit 1 is not considering to be technically feasible.

As stated above, increasing the limestone feed rate for Unit 2 is technically feasible, but would need to be done in tandem with increasing the liquid-to-gas (L/G) ratio, since Unit 2 is not currently operating at its maximum design L/G ratio. Only three of the four recycle pumps have been operating at a time. Increasing the amount of fresh limestone added to the system in tandem with increasing the L/G ratio would provide a performance rate improvement of 0.01 lb SO₂ per MMBtu. This equates to an 11% reduction in SO₂ emissions from the baseline scenario of 0.08 lb SO₂ per MMBtu. Increasing the Ca:S stoichiometric ratio in tandem with increasing the L/G ratio is considered a technically feasible SO₂ control option for LOS Unit 2.

Regarding design changes, it is not technically feasible to add an additional spray level or to optimize the spray level coverage for Unit 1 or Unit 2. There is no room for an additional spray level on either unit. After reviewing the operations at LOS, the original equipment manufacturer of LOS's WFGD spray coverage concluded that no additional improvements could be made to the spray nozzle design that would reduce SO₂ emissions. Therefore, adding an additional spray level and optimizing the spray level coverage are not considered to be technically feasible SO₂ control strategies and will not be considered further.

The use of dibasic acid (DBA), a pH buffer additive, in conjunction with increasing the rate of injection of fresh limestone is expected to reduce SO₂ emissions at both Unit 1 and Unit 2.

Unit 1 could achieve a performance rate of 0.06 lb SO₂ per MMBtu using DBA in conjunction with increasing the fresh limestone injection rate. This equates to a 38% reduction in SO₂ emissions from the baseline scenario of 0.09 lb SO₂ per MMBtu. A pH buffer additive is considered a technically feasible SO₂ control option for LOS Unit 1.

Unit 2 could achieve a performance rate of 0.05 lb SO₂ per MMBtu using DBA in conjunction with increasing the fresh limestone injection rate. This equates to a 41% reduction in SO₂ emissions from the baseline scenario of 0.08 lb SO₂ per MMBtu. A pH buffer additive is considered a technically feasible SO₂ control option for LOS Unit 2.

4.2 Step 1 – Cost of Compliance

The cost of compliance and incremental cost of compliance for the reasonable progress controls are listed in Table 16 (Unit 1) and Table 17 (Unit 2).

Table 16: SO₂ Cost of Compliance and Incremental Cost of Compliance (Unit 1)

Control Technology	Performance Rate (lb SO ₂ /MMBtu)	Annual Emission Reduction (tpy)	Annualized Total Cost (\$)	Cost of Compliance (\$/ton)	Incremental Cost of Compliance (\$/ton)
WFGD (Baseline)	0.09				
Ca:S Stoichiometry	0.08	59	752,000	12,698	
pH Buffer Additive	0.06	237	4,833,418	20,357	22,902

Table 17: SO₂ Cost of Compliance and Incremental Cost of Compliance (Unit 1)

Control Technology	Performance Rate (lb SO ₂ /MMBtu)	Annual Emission Reduction (tpy)	Annualized Total Cost (\$)	Cost of Compliance (\$/ton)	Incremental Cost of Compliance (\$/ton)
WFGD (Baseline)	0.09				
Ca:S Stoichiometry and L/G Ratio	0.08	128	1,439,000	11,264	
pH Buffer Additive	0.05	464	8,287,368	17,843	20,340

A detailed breakdown of the costs listed in Table 16 and Table 17 can be found in Basin's submitted four factors analysis.¹¹ The Department has reviewed these costs and believes them to be accurate.

Ca:S stoichiometric adjustments on Unit 1 would provide a potential 10% reduction in emissions from the baseline scenario. This would result in approximately 60 tons of SO₂ being reduced at an annualized cost of approximately \$752,000, equating to approximately \$12,700 per ton of SO₂ reduced. This control option does not provide a significant reduction in emissions.

Ca:S stoichiometric adjustments in tandem with increasing the L/G ratio on Unit 2 would provide a potential 11% reduction in emissions from the baseline scenario. This would result in approximately 130 tons of SO₂ being removed at an annualized cost of approximately \$1.4 million, equating to approximately \$11,300 per ton of SO₂ reduced.

Incorporation of a pH buffer additive on Unit 1 would provide a potential 38% reduction in emissions from the baseline scenario. This would result in approximately 240 tons of SO₂ being reduced at an annualized cost of approximately \$4.8 million, equating to approximately \$20,400 per ton of SO₂ reduced.

Incorporation of a pH buffer additive on Unit 2 would provide a potential 41% reduction in emissions from the baseline scenario. This would result in approximately 460 tons of SO₂ being reduced at an annualized cost of approximately \$8.3 million, equating to approximately \$17,800 per ton of SO₂ reduced.

¹¹ Appendix B.3.b. Appendix C. PDF page 482.

4.3 Step 2 – Time Necessary for Compliance

A summary of the anticipated timelines for the installation of the technically feasible control technologies for Unit 1 is provided in Table 18.

Table 18: Time Required for SO₂ Controls (Unit 1)

Control Technology	Total time after SIP approval (months)
Ca:S Stoichiometry	3
pH Buffer Additive	12

The anticipated timelines for the installation of each of the control technologies indicates all options could be installed prior to the end of the second planning period.

A summary of the anticipated timelines for the installation of the technically feasible control technologies for Unit 2 is provided in Table 19.

Table 19: Time Required for SO₂ Controls (Unit 2)

Control Technology	Total time after SIP approval (months)
Ca:S Stoichiometry and L/G Ratio	3
pH Buffer Additive	12

The anticipated timelines for the installation of each of the control technologies indicates all options could be installed prior to the end of the second planning period.

4.4 Step 3 – Energy and Non-Air Quality Environmental Impacts

4.4.1 Energy

Adjustment of the Ca:S stoichiometric ratio would require an increased operation of the recycle pump, which will increase the auxiliary power requirements. This would adversely affect the net plant heat rate. This impact is significant but not significant enough to eliminate adjustment of the Ca:S stoichiometric ratio as a control option.

4.4.2 Non-Air Quality Environmental Impacts

There are no known significant non-air quality environmental impacts associated with any of the technically feasible SO₂ control technologies.

4.5 Step 4 – Remaining Useful Life

Based on the information provided to the Department, LOS is expected to operate beyond the life of the control equipment. Therefore, remaining useful life was not considered.

A.4 – CCS

1 Introduction and Representative Operations

Coal Creek Station (CCS) is a two-unit electrical generating utility (EGU). Each unit has the capacity to produce approximately 605 megawatts (MW) of power on a gross basis. Unit 1 and Unit 2 are identical Combustion Engineering boilers firing pulverized lignite coal tangentially. Unit 1 has a heat input capacity of 6,015 MMBtu per hour; Unit 2 has a heat input capacity of 6,022 MMBtu per hour. Unit 1 began commercial operation in 1979. Unit 2 began commercial operation in 1980. CCS is located in south central McLean County about five miles south of the town of Underwood, North Dakota and approximately three miles west of US Highway 83. CCS receives its lignite coal from the Falkirk Mine that is operated by the Falkirk Mining Company, which is a subsidiary of the North American Coal Corporation.

The average annual amount of North Dakota lignite coal combusted at CCS from 2009 through 2018 was approximately 7.2 million tons. See Table 1 for detailed information.

Table 1: Yearly Coal Combusted (tons)

Year	Unit 1 (tons)	Unit 2 (tons)
2009	4,095,584	3,941,997
2010	3,835,877	3,284,752
2011	4,371,455	4,801,722
2012	3,645,837	3,579,986
2013	3,623,564	3,304,313
2014	3,407,090	3,528,472
2015	3,439,201	3,446,814
2016	3,355,393	2,862,056
2017	2,752,937	3,394,443
2018	3,750,337	3,667,824
Average	3,627,728	3,581,238
Combined Average	7,208,966	

Over the same 10-year period (2009–2018), CCS operated at an 87% annual capacity factor (ACF), as determined on an actual heat input basis. Based on information provided to the North Dakota Department of Environmental Quality, Division of Air Quality (Department), future operations are expected to be consistent with this 10-year period and the 87% annual capacity factor was used when calculating the baseline and future projected emissions discussed in Section 2.

Table 2 displays the operational information from 2009–2018. The ACF is calculated by dividing the actual heat input by the maximum potential heat input for Unit 1 (52.69×10^6 MMBtu/yr) and Unit 2 (52.75×10^6 MMBtu/yr).

Table 2: Utilization and Annual Capacity Factor

Year	Unit 1 Heat Input (MMBtu/yr)	Unit 2 Heat Input (MMBtu/yr)	Unit 1 Annual Capacity Factor	Unit 2 Annual Capacity Factor
2009	49,625,416	48,220,581	0.94	0.91

Year	Unit 1 Heat Input (MMBtu/yr)	Unit 2 Heat Input (MMBtu/yr)	Unit 1 Annual Capacity Factor	Unit 2 Annual Capacity Factor
2010	49,409,811	41,998,558	0.94	0.80
2011	43,014,802	46,942,626	0.82	0.89
2012	48,676,811	47,951,409	0.92	0.91
2013	48,686,810	43,924,548	0.92	0.83
2014	46,286,312	46,530,063	0.88	0.88
2015	47,059,790	46,053,317	0.89	0.87
2016	45,437,239	38,498,049	0.86	0.73
2017	37,327,033	44,826,636	0.71	0.85
2018	48,250,097	47,761,484	0.92	0.91
Average	46,377,412	45,270,727	0.88	0.86
		Combined Average	0.87	

2 SO₂ Emissions Controls and History

CCS commenced operation in 1979 when Unit 1 was started up. As is stated above, Unit 2 was started up in 1980. CCS was deemed BART eligible in round 1 of Regional Haze and an analysis determined that 0.15 lb/MMBtu of SO₂ as a 30-day rolling average met BART requirements. CCS currently operates four-module wet flue gas desulfurization scrubbers to comply with the 0.15 lb/MMBtu SO₂ limit.

2.1 SO₂

2.1.1 SO₂ Emissions Controls

CCS is equipped with wet flue gas desulfurization (WFGD) for SO₂ control on Unit 1 and Unit 2. CCS also utilizes DryFining™, a multi-pollutant control technology. DryFining™ provides a heat input reduction that correspondingly decreases the amount of flue gas created in the combustion process. In 2017 a novel flue gas reheat system was installed. This allows for an additional proportion of gas to be routed to the wet scrubber instead of having to bypass, providing a decrease in the lb/MMBtu SO₂ emission rate.¹ Both exhaust stacks are equipped with a SO₂ continuous emissions monitoring system (CEMS).

2.1.2 SO₂ Emissions History

June 2017 through December 2018 was used to determine the SO₂ baseline emissions rate from CCS. This time period was chosen since it serves as the best representation of expected emissions and performance rate of the WFGD operations. This information is displayed in Table 3.

Table 3: SO₂ emissions

Year	Unit 1 Emissions		Unit 2 Emissions	
	lb SO ₂ /MMBtu	tons SO ₂	lb SO ₂ /MMBtu	tons SO ₂
2017	0.14	1,938	0.14	1,793
2018	0.14	3,458	0.14	3,400

¹ Appendix B.4.b, p 5. PDF page 1051.

Year	Unit 1 Emissions		Unit 2 Emissions	
	lb SO ₂ /MMBtu	tons SO ₂	lb SO ₂ /MMBtu	tons SO ₂
Baseline	0.14	2,698	0.14	2,596

The average emissions rate of 0.14 lb SO₂ per MMBtu is representative of future expected operations. This value is used as the starting point when determining the cost of compliance for the add-on controls evaluated in Section 3.2.

3 SO₂ Analysis

3.1 SO₂ Technologies

The reasonable progress controls that were identified for analysis for CCS Unit 1 and Unit 2 are listed in Table 4, along with their approximate annual control efficiency. All controls were deemed technically feasible.

Table 4: SO₂ Controls Identified for Analysis

Control Technology	Approximate Annual Control Efficiency
Dry Sorbent Injection	50-70%
Spray Dry Absorption	70-90%
Natural Gas Reheat System	96%
New Wet Stack	96%

CCS currently utilizes a minor bypass in limited situations to maintain dry stack conditions. A natural gas reheat system or new wet stacks would theoretically remove the need for this bypass, maximizing the proportion of flue gas to the wet scrubber.² Both methods were analyzed as potential options and result in the same control efficiency. The existing WFGD system currently achieves an annual average removal efficiency of approximately 94% to 95%.³ Dry sorbent injection and spray dry absorption would not provide improvement over CCS's existing SO₂ emissions control system and were not evaluated further.

3.1.1 New Wet Stack

One control option that was analyzed was the replacement of the current stacks on Unit 1 and Unit 2. CCS Unit 1 and Unit 2 are both dry stacks, despite using a wet scrubber. Converting the existing stacks to a wet stack design is not possible and instead new wet stacks would need to be constructed and the current stacks would be abandoned and demolished. For the evaluation of a new wet stack, Hamon Custodis, Inc. provided an initial high-level concept to effectively replace the two existing stacks with a rough budget price. CCS has added to this price a high-level and conservatively low set of cost estimates to convert the Custodis cost to an appropriate diameter and

² Appendix B.4.b, pp 25-26. PDF pages 1071-1072.

³ Appendix B.4.b, p 25. PDF page 1071.

to include foundations, duct work, and continuous emissions monitoring systems (CEMS).⁴ A new wet stack would result in an approximate 1,377 ton per year reduction of SO₂.

3.1.2 Natural Gas Reheat System

CCS Units 1 and 2 currently utilize a novel flue gas reheat system that can maintain a dry stack under most operating situations, while maximizing the proportion of flue gas to the wet scrubber. During low load and cold weather operation, the existing reheat system does not provide enough thermal energy to reheat the stack gas to a dry state. The existing reheat system adds approximately 11 MMBtu/hr, and CCS estimates that approximately 31.5 MMBtu/hr of additional energy would be required to maintain a dry stack under all operating conditions. WBI Energy provided a cost estimate for a new gas line, with the cost split between both units. Barr Engineering provided an estimate for the natural gas-fired duct burner system, with additional consideration for site-specific installation factors.⁵ The installation of a new natural gas reheat system would result in an approximate 1,377 ton per year reduction of SO₂.

3.2 Step 1 – Cost of Compliance

The cost of compliance and incremental cost of compliance for the reasonable progress controls are listed in Table 5.

Table 5: SO₂ Cost of Compliance and Incremental Cost of Compliance

Control Technology	Performance Rate (lb SO₂/MMBtu)	Annual Emission Reduction (tpy)	Annualized Total Cost (\$)	Cost of Compliance (\$/ton)
WFGD(Baseline)	0.14			
New Wet Stack	0.08	1,377	3,979,749	2,890
Natural Gas Reheat System	0.08	1,377	3,388,308	2,460

A detailed breakdown of the costs listed in Table 5 can be found in Great River Energy's submitted four factors analysis.⁶ The Department has reviewed these costs and believes them to be accurate.

A new wet stack would result in a cost of compliance value of \$2,890 per ton of SO₂ removed. A new natural gas reheat system would result in a cost of compliance value of \$2,460 per ton of SO₂ removed.

3.3 Step 2 – Time Necessary for Compliance

Both the new wet stack and natural gas reheat system would require at least two to three years to engineer, permit, and install the equipment. Therefore, time necessary for compliance is not a limiting factor when determining additional reasonable controls. The anticipated timeline would allow for either option to be installed prior to the end of the second round of regional haze.

⁴ Appendix B.4.b, p 26. PDF page 1072.

⁵ Appendix B.4.b, pp 26-27. PDF pages 1072-1073.

⁶ Appendix B.4.b. Appendix A. PDF page 1078.

3.4 Step 3 – Energy and Non-Air Quality Environmental Impacts

The replacement wet stack would result in the demolition and disposal of a significant amount of materials with associated use of demolition equipment and portable engines to accommodate these activities.

The natural gas-fired reheat system would result in additional non-SO₂ pollutant emissions from the combustion of natural gas onsite. Potential NO_x emissions are estimated to be between 14 and 27 tons per year.⁷

The energy and non-air quality environmental impacts from the new wet stack or the natural gas reheat system are significant but do not significant enough to remove the control technology from consideration.

3.5 Step 4 – Remaining Useful Life

For the purposes of this analysis, a 20-year life was used for CCS to calculate emission reductions, amortized costs, and cost effectiveness. Therefore, remaining useful life does not need to be considered for the purposes of round 2 planning.

⁷ Appendix B.4.b, p 29. PDF page 1075.

A.5 – Minnkota MRY

1 Introduction and Representative Operations

Minnkota Power Cooperative, Inc. (Minnkota) – Milton R. Young Station (MRYS) is a two-unit electrical generating station. Unit 1 is a Babcock & Wilcox cyclone-fired boilers fired on lignite coal. Unit 1 commenced commercial operation in 1970. Unit 1 has a turbine-generator nameplate rating of 257 megawatts (MW) and a nominal rated heat input capacity of 3,200 MMBtu per hour. MRYS is located approximately five miles southeast of the town of Center, North Dakota. MRYS receives lignite from BNI Coal, Ltd's Center Mine, which is located adjacent to the facility.

The average annual amount of North Dakota lignite coal combusted at MRYS Unit 1 from 2009 through 2018 was 1.5 million tons. See Table 1 for detailed information.

Table 1: MRYS Unit 1 Coal Combusted

Year	Coal Combusted (tons)
2009	1,324,257
2010	1,582,806
2011	1,408,716
2012	1,610,825
2013	1,465,413
2014	1,545,188
2015	1,373,362
2016	1,683,786
2017	1,626,840
2018	1,320,317
Average	1,494,151

Over this same period (2009–2018), MRYS Unit 1 operated at a 70% annual capacity factor (ACF), as determined on an actual heat input basis. Future operations are expected to be consistent with this 10-year period and the 70% annual capacity factor was used when calculating the baseline and future projected emissions discussed in Section 2.

Table 2 displays the operational information from 2009-2018. The ACF is calculated by dividing the actual heat input by the maximum potential heat input of 28.0×10^6 MMBtu per year.

Table 2: Utilization and Annual Capacity Factor

Year	Actual Heat Input (MMBtu/yr)	Annual Capacity Factor
2009	17,449,077	0.62
2010	20,765,112	0.74
2011	18,534,017	0.66
2012	20,670,979	0.74
2013	18,864,309	0.67

Year	Actual Heat Input (MMBtu/yr)	Annual Capacity Factor
2014	19,129,722	0.68
2015	17,646,175	0.63
2016	23,097,486	0.82
2017	21,628,091	0.77
2018	17,453,674	0.62
Average	19,523,864	0.70

2 NO_x and SO₂ Emissions Controls and Representative History

MRYS Unit 1 commenced commercial operation in 1970. In April 2006, the Environmental Protection Agency, Department of Justice and the State of North Dakota, reached a Clean Air Act (CAA) major New Source Review Program settlement with Minnkota Power Cooperative and Square Butte Power Cooperative. Minnkota was required to spend approximately \$100 million to install or upgrade state-of-the-art pollution controls between the time of the settlement and 2011. Minnkota was also required to reduce 23,561 tons per year (tpy) of SO₂ by 2012, 9,458 tpy of NO_x by 2010, and to comply with declining plant-wide caps for SO₂. The proposed Consent Decree requirements were incorporated into enforceable permits. The agreement resolved CAA violations that occurred at MRYS. MRYS was deemed BART-eligible in the first round of the regional haze program.

2.1 NO_x

2.1.1 NO_x Emissions Controls

MRYS Unit 1 is equipped with Advanced Separated Over Fire Air (ASOFA) and selective non-catalytic reduction (SNCR) for NO_x control. These were the BART controls selected in the first round of the Regional Haze program.¹ Minnkota previously entered into a Consent Decree that required MRYS to install BACT for NO_x, which was determined to be SNCR with ASOFA.^{2,3}

2.1.2 NO_x Emissions History

To determine the baseline emission rates, the time period of 2016-2018 was used. These results are shown in Table 3, along with the NO_x emissions for each year.

Table 3: Annual NO_x Rate and Emissions

Year	Emissions Rate (lb/MMBtu)	NO_x Emissions (tons)
2016	0.33	3,841
2017	0.33	3,579
2018	0.33	2,924
Average	0.33	3,448

¹ North Dakota State Implementation Plan for Regional Haze, March 3, 2010, p. 74.

² Available at: <https://www.epa.gov/enforcement/minnkota-power-cooperative-and-square-butte-electric-cooperative-settlement> (Last visited March 23, 2021)

³ North Dakota State Implementation Plan for Regional Haze, March 3, 2010, Appendix B.4, p.16-19.

The baseline was established in consultation with the NDDEQ. It is the most recent time period that includes two non-major outage years, and one major outage year. Outages on these units follow a three-year cycle, so the time period of 2016-2018 is the most representative of future expected emissions.⁴ The average emissions rate of 0.33 lb NO_x per MMBtu is used as the starting point when determining the cost for the add-on controls evaluated in Section 3.2.

2.2 SO₂

2.2.1 SO₂ Emissions Controls

MRYS Unit 1 is equipped with wet flue gas desulfurization (WFGD) for SO₂ control. This control technology was installed in 2011 as a result of the BART determination made in the first round of the Regional Haze program.⁵ The WFGD system typically achieves an annual removal efficiency of approximately 97% and complies with a 30-day rolling average 95% SO₂ removal efficiency.⁶

2.2.2 SO₂ Emissions History

To determine the baseline emission rates, the time period of 2016-2018 was used. These results are shown in Table 4, along with the SO₂ emissions for each year.

Table 4: Annual SO₂ Emissions Rate

Year	Emissions Rate (lb/MMBtu)	SO ₂ Emissions (tons)
2016	0.08	909
2017	0.08	905
2018	0.06	518
Average	0.07	777

The average emission rate of 0.07 lb SO₂ per MMBtu is representative of future expected operations and is used as the starting point when determining the cost of compliance for the additional controls evaluated in Section 4.2. Note that the tons of SO₂ listed in Table 4 do not equal the calculated tons used for the baseline emissions (Table 8). The baseline emissions are calculated using the recent emissions rate with the average ACF over the last 10 years. This results in a difference of approximately 60 tons of SO₂.

3 NO_x Analysis

3.1 NO_x Technologies

The reasonable progress controls evaluated by MRYS for Unit 1 are listed in Table 5. Performance rate and expected annual emissions are included for both control technologies that were determined to be technically feasible. MRYS evaluated optimizing their current SNCR control technologies as well as adding Rich Reagent Injection (RRI). Note that the expected annual emissions in Table 5 were calculated using the performance rate, potential heat input, and the ACF (Table 2).

⁴ Appendix B.5.b., p. 1-4. PDF page 1157.

⁵ North Dakota State Implementation Plan for Regional Haze, March 3, 2010, p. 71.

⁶ Appendix B.5.b., p. 3-3 – 3-4. PDF page 1179-1180.

Therefore, the tons of NO_x emissions are different than the tons of NO_x emissions displayed in Table 3 since the table below contains calculated emissions based on representative operations..

Table 5: Reasonable Progress NO_x Controls

Control Technology	Performance Rate (lb/MMBtu)	Emissions (tons/year)
SNCR/ASOFA (baseline)	0.33	3,241
Optimized SNCR/ASOFA	0.33	3,221
RRI/SNCR/ASOFA	0.28	2,733

Selective catalytic reduction (SCR) was identified as a potential NO_x control technology but was deemed technically infeasible at MRYS in the previous BART and BACT analysis. No new information or experience has occurred since those analyses to change the conclusions that were made. SCR remains technically infeasible at MRYS.⁷

3.1.1 Optimization of Selective Non-Catalytic Reduction (SNCR)

Utilizing operating and vendor experience acquired since the original installation, enhancements to the existing system were identified to potentially reduce NO_x emission rates. Enhancements include changing the nozzles on existing lances, replacing the existing lances, adding lances in new locations and allowing for higher ammonia slip rates. Higher ammonia slip rates would allow for higher levels of urea injection, potentially reducing NO_x emission rates further. The ASOFA system would be operated in conjunction with the optimized SNCR system. These enhancements are projected to amount to minimal NO_x reductions per year. The optimization of SNCR was deemed technically feasible.

3.1.2 Rich Reagent Injection (RRI)

RRI is a NO_x emission control technology specifically intended for use on cyclone boilers. RRI adds dilute urea reagent to the hot boiler gases near the cyclones. This location must be devoid of free oxygen to avoid oxidation of the urea, which results in the formation of additional NO_x.⁸

The use of RRI control technology in conjunction with SNCR and ASOFA results in a 16% reduction in NO_x emissions from the baseline scenario. The expected performance rate would drop from 0.33 to 0.28 lb NO_x per MMBtu. The 0.28 lb per MMBtu performance rate was determined using MRYS unit-specific operations. Maximum NO_x reductions from both RRI and SNCR systems occur when the boiler is at or near full load, and in a steady-state condition. Emission rates stated by vendors are based on these conditions, and do not always account for site specific operating conditions. RRI's operational effectiveness depends on oxygen-deprived conditions. Both Unit 1 and Unit 2 at MRYS are designed to still be able to achieve full load even if one cyclone burner is out of service. This situation is not unusual during routine maintenance. When this occurs however, air can leak through

⁷ Appendix B.5.b., p. 2-3. PDF page 1163.

⁸ Appendix B.5.b., p. 2-3. PDF page 1163.

the combustion air dampers of an out-of-service cyclone and will result in the increase of NO_x formation, due to the addition of oxygen in the fuel-rich zone of the in-service boiler.⁹

Another problem MRYS encounters with RRI and other control technologies, is that MRYS is a mine-mouth plant that utilizes run-of-mine fuel. This results in significant coal quality variability. These variations can lead to cyclones becoming fouled, meaning that insufficient temperature exists for the slag to flow properly from the cyclone. When this occurs, fuel oil is co-burned in the fouled cyclone which results in increased oxygen levels in the fuel-rich zone. This leads to additional formation of NO_x.¹⁰ While these factors impact the performance rate for NO_x, the installation of RRI with SNCR and ASOFA was deemed technically feasible under limited conditions and will be evaluated further.

3.2 Step 1 – Cost of Compliance

The cost of compliance and incremental cost for the reasonable progress controls are listed in Table 6. Cost estimates are based on a vendor proposal and were calculated based on a 20-year project life.

Table 6: NO_x Cost of Compliance and Incremental Cost of Compliance

Control Technology	Performance Rate (lb/MMBtu)	Annual Emission Reduction (tpy)	Annualized Total Cost (\$)	Cost of Compliance (\$/ton)	Incremental Cost of Compliance (\$/ton)
SNCR/ASOFA (Baseline)	0.33				
Optimized SNCR/ASOFA	0.33	20	1,996,685	102,269	
RRI/SNCR/ASOFA	0.28	508	5,996,594	11,813	8,195

A detailed breakdown of the costs listed in Table 6 can be found in Minnkota's submitted four factor analysis.¹¹ The Department has reviewed these costs and believes them to be accurate.

MRYS relied on a vendor proposal for cost estimates to account for certain site-specific costs that would be incurred implementing these NO_x control technologies. In the case of optimizing the SNCR, the detailed vendor evaluation identified new recommended SNCR injection locations, along with current nozzle and lance enhancements. The resulting annualized cost is approximately \$2,000,000, with 83% of that being attributed to the cost of urea reagent. These changes would result in an annual reduction of approximately 20 tons of NO_x, and a cost of compliance value of approximately \$102,000 per ton of NO_x reduced.

The implementation of RRI with the SNCR and ASOFA systems would result in an approximate annual reduction of 500 tons of NO_x. The annualized total cost is approximately \$6,000,000, with a cost of compliance at \$11,800 per ton of NO_x reduced. MRYS submitted its original four-factor analysis on January 31, 2019. NDDEQ questioned the excessive cost estimates for RRI at that time. In the revised four-factor analysis that was submitted on May 29, 2019, MRYS defended these

⁹ Appendix B.5.b, p. 2-5. PDF page 1165.

¹⁰ Appendix B.5.b, p. 2-5. PDF page 1165.

¹¹ Appendix B.5.b. Appendix A. PDF page 1196 and 1211.

estimates. The cost estimates are site-specific and utilized computational fluid dynamic (CFD) modeling and boiler mapping along with vendor proposals.¹² The CFD modeling, boiler mapping, and RRI injection analysis determined that the necessary injection locations needed are not in easily accessible locations on either unit. This results in added cost for new platforms and stairs to access new injection locations, significant new piping for increased urea, cooling water, dilution water and atomization air, expansion of the microfiltration and reverse osmosis water system, and supply and installation of the boiler bent tube openings for the new RRI and SNCR injectors.¹³ Minnkota firmly believes that these costs are accurate and represent the actual costs for installation and implementation of RRI with SNCR and ASOFA.

3.3 Step 2 – Time Necessary for Compliance

The time necessary for compliance is not a limiting factor when determining additional reasonable controls for MRYS Unit 1 NO_x emissions since SNCR optimization and/or RRI could be installed prior to the end of the second planning period.

3.4 Step 3 – Energy and Non-Air Quality Environmental Impacts

3.4.1 Energy

The primary energy impact of utilizing RRI with SNCR or optimizing existing SNCR system is reduced boiler efficiency due to evaporation of large amounts of dilute urea. This results in excess coal needing to be burned to evaporate the expected amount of dilute urea in the boiler. An incremental increase in energy will also result from providing more compressed air for reagent atomization. Auxiliary power requirements result in a 66 kW increase in an optimized SNCR, and a 132 kW increase with RRI and SNCR.¹⁴ These energy impacts are only incrementally higher than the existing system, and do not remove either option from consideration.

3.4.2 Non-Air Quality Environmental Impacts

Non-air quality impacts of the control technologies are very similar to the impacts of the existing SNCR system. There may be an increase in ammonia slip, but a majority will be captured in the WFGD system. There will also be additional reverse osmosis/condensate waste due to the increase in demand from the systems and the need to dilute concentrated urea. This would result in millions of gallons of additional water treatment wastewaters being discharged from the MRYS facility on an annual basis. These impacts are considered acceptable and do not remove either option from consideration.

3.5 Step 4 – Remaining Useful Life

Based on the information provided to the Department, MRYS is expected to operate beyond the life of the control equipment. Therefore, remaining useful life was not considered.

¹² Appendix B.5.b., p. 2-4. PDF page 1164.

¹³ Appendix B.5.b., p.2-7. PDF page 1167.

¹⁴ Appendix B.5.b., p. 2-14. PDF page 1174.

4 SO₂ Analysis

4.1 SO₂ Technologies Evaluated

The reasonable progress controls that were identified for analysis for MRYS Unit 1 are listed in Table 7, along with their approximate annual control efficiency. A new WFGD was not evaluated for Unit 1, as the current system was installed in 2011. All controls were deemed technically feasible.

Table 7: SO₂ Controls Identified for Analysis

Control Technology	Approximate Annual Control Efficiency
ReACT Scrubber	92-98%
Modification of Existing WFGD	96-98%
Circulating Semi-Dry FGD	90-97%
Semi-Dry FGD	90-95%

As discussed in Section 2.2.1, the existing WFGD system currently achieves an annual average removal efficiency of approximately 97%. The approximate annual control efficiencies listed in Table 7 start from an estimate of uncontrolled SO₂ emissions based on inlet sulfur concentration.

4.1.1 Semi-Dry Flue Gas Desulfurization

Semi-dry FGD technology is an alternative to WFGD technology in SO₂ emission control. Spray Dryer Absorber (SDA) is the most common semi-dry FGD system. Circulating Dry Scrubber is another variation of the semi-dry process. SDA technology has never been clearly demonstrated to achieve the same SO₂ removal levels as WFGD technology.¹⁵ The CDS system can achieve better control efficiency than the SDA process, but only achieves similar levels to those of the current WFGD system. Because the semi-dry FGD technologies achieve less or equal SO₂ removal to that of the current WFGD system, neither was evaluated further.

4.1.2 Regenerative Activated Coke Technology

Regenerative Activated Coke Technology (ReACT) is a multipollutant control system that utilizes activated coke to remove SO₂, NO_x and mercury. The ReACT process has been demonstrated to achieve 99% SO₂ removal on low sulfur coal units. However, the supplier of the ReACT process determined that MRYS is not a good candidate for the technology. MRYS factors that would impact the performance and cost of ReACT are that the inlet temperature is too high, higher oxidation of the activated coke would be expected, and the sulfuric acid production rates would be very high.¹⁶ MRYS also utilizes high sulfur coal.¹⁷ ReACT has only been applied on low sulfur fuel, and pilot tests on high sulfur coal have only shown 92-98% SO₂ removal rates. Because these levels could be achieved by the existing wet FGD system, ReACT was not evaluated further.

¹⁵ Appendix B.5.b., p. 3-5. PDF page 1181.

¹⁶ Appendix B.5.b., p. 3-5. PDF page 1181.

¹⁷ Appendix B.5.b., p. 3-5. PDF page 1181.

4.1.3 Modification of Existing Wet FGD (WFGD) System

The original equipment manufacturer for the existing WFGD system on Unit 1 evaluated potential modifications that could increase the SO₂ removal efficiency of the system. The upgrades that were evaluated include increasing the liquid-to-gas ratio, installation of new types of spray nozzles, running additional pumps, and adjusting the operating conditions of the scrubber. The evaluation determined that Unit 1 could achieve 97.4% SO₂ removal by increasing the Calcium/Sulfur stoichiometry to 1.025¹⁸ and replacing three of four recirculation pump motors to increase the liquid to gas ratio in the scrubber.¹⁹ This modification was deemed technically feasible and was evaluated further. The performance rate and SO₂ annual emissions are shown for this technology and the baseline in Table 8. Note that the expected annual emissions in Table 8 were calculated using the performance rate, potential heat input, and the ACF (Table 2). Therefore, the tons of SO₂ emissions are different than the tons of SO₂ emissions displayed in Table 4 since the table below contains calculated emissions based on representative operations..

Table 8: Reasonable Progress SO₂ Controls

Control Technology	Performance Rate (lb/MMBtu)	Emissions (tons/year)
WFGD (Baseline)	0.07	721
Modify WFGD	0.06	595

4.2 Step 1 – Cost of Compliance

The cost of compliance for modification of the existing WFGD is shown in Table 9.

Table 9: SO₂ Cost of Compliance

Control Technology	Performance Rate (lb/MMBtu)	Annual Emission Reduction (tpy)	Annualized Total Cost (\$)	Cost of Compliance (\$/ton)
WFGD	0.074			
Modified WFGD	0.061	126	365,562	2,903

A detailed breakdown of the costs listed in Table 9 can be found in Minnkota's submitted four factor analysis.²⁰ The Department has reviewed these costs and believes them to be accurate.

The cost estimates for modifying the existing WFGD system were provided by the original equipment manufacturer. These costs were supplemented with engineering estimates for installation from Burns & McDonnell. The cost estimates are limited to these factors and assumes that all other existing systems, including the existing electrical system, are capable of supporting the modifications with no further upgrades.²¹ It is also assumed that no change in operating staff will

¹⁸ Appendix B.5.b., p. 3-4. PDF page 1180.

¹⁹ Appendix B.5.b., p.3-9. PDF page 1185.

²⁰ Appendix B.5.b., p.3-9 – 3-13. PDF page 1185-1189.

²¹ Appendix B.5.b., p. 3-9. PDF page 1185.

occur from the modifications. These conservative estimates result in a cost of compliance value of \$2,900 per ton of SO₂ removed.

4.3 Step 2 – Time Necessary for Compliance

The process to bid, design, purchase, and install retrofits to an existing WFGD system can take two to three years.²² The time necessary for compliance is not a limiting factor when determining additional reasonable controls for MRYS Unit 1 SO₂ emissions since the WFDG could be modified prior to the end of the second planning period.

4.4 Step 3 – Energy and Non-Air Quality Environmental Impacts

4.4.1 Energy

Modifying the existing WFGD will result in an energy demand increase of 586 kW, a 0.3% increase in the percent of nominal generation. This increase is acceptable and does not remove WFGD modification as a control option.

4.4.2 Non-Air Quality Environmental Impacts

Modifying the existing WFGD system will have similar non-air quality environmental impacts to those of the existing system. However, there will be an incremental increase in the solids disposal rate as additional removal of SO₂ will result in increased byproduct. This is not a significant impact and does not remove the control technology from consideration.

4.5 Step 4 – Remaining Useful Life

Based on the information provided to the Department, MRYS is expected to operate beyond the life of the control equipment. Therefore, remaining useful life was not considered.

²² Appendix B.5.b., p. 3-14. PDF page 1190

1 Introduction and Representative Operations

Minnkota Power Cooperative, Inc. (Minnkota) – Milton R. Young Station (MRYS) is a two-unit electrical generating station. Unit 2 is a Babcock & Wilcox cyclone-fired boilers fired on lignite coal. Unit 2 commenced commercial operation in 1977. Unit 2 has a turbine-generator nameplate rating of 477 MW and a nominal rated heat input capacity of 6,300 MMBtu per hour. MRYS is located approximately five miles southeast of the town of Center, North Dakota. MRYS receives lignite from BNI Coal, Ltd's Center Mine, which is located adjacent to the facility.

The average annual amount of North Dakota lignite coal combusted at MRYS Unit 2 from 2009 through 2018 was 2.6 million tons. See Table 1 for detailed information.

Table 1: MRYS Unit 2 Coal Combusted

Year	Coal Combusted (tons)
2009	2,690,168
2010	2,119,700
2011	2,949,190
2012	2,746,928
2013	2,102,746
2014	2,290,214
2015	2,845,985
2016	2,160,413
2017	3,010,361
2018	2,978,138
Average	2,589,384

Over this same period (2009–2018), MRYS Unit 2 operated at a 61% annual capacity factor (ACF), as determined on an actual heat input basis. Future operations are expected to be consistent with this 10-year period and the 61% annual capacity factor was used when calculating the baseline and future projected emissions discussed in Section 2.

Table 2 displays the operational information from 2009–2018 for Unit 2. The ACF is calculated by dividing the actual heat input by the maximum potential heat input of 55.1×10^6 MMBtu per year.

Table 2: Utilization and Annual Capacity Factor

Year	Actual Heat Input (MMBtu/yr)	Annual Capacity Factor
2009	36,697,676	0.66
2010	29,507,936	0.53
2011	41,664,019	0.75
2012	34,923,781	0.63

Year	Actual Heat Input (MMBtu/yr)	Annual Capacity Factor
2013	26,539,099	0.48
2014	29,840,051	0.54
2015	36,389,744	0.66
2016	26,618,855	0.48
2017	38,455,791	0.70
2018	37,990,222	0.69
Average	33,862,717	0.61

2 NO_x and SO₂ Emissions Controls and Representative History

MRYS Unit 2 commenced commercial operation in 1977. In April 2006, the Environmental Protection Agency, Department of Justice and the State of North Dakota, reached a Clean Air Act (CAA) major New Source Review Program settlement with Minnkota Power Cooperative and Square Butte Power Cooperative. Minnkota was required to spend approximately \$100 million to install or upgrade state-of-the-art pollution controls between the time of the settlement and 2011. Minnkota was also required to reduce 23,561 tons per year (tpy) of SO₂ by 2012, 9,458 tpy of NO_x by 2010, and to comply with declining plant-wide caps for SO₂. The proposed Consent Decree requirements were incorporated into enforceable permits. The agreement resolved CAA violations that occurred at MRYS. It was deemed BART-eligible in the first round of the regional haze program.

2.1 NO_x

2.1.1 NO_x Emissions Controls

MRYS Unit 2 is equipped with Advanced Separated Over Fire Air (ASOFA) and selective non-catalytic reduction (SNCR) for NO_x control. These were the BART controls selected in the first round of the Regional Haze program.¹ Minnkota previously entered into a Consent Decree that required MRYS to install BACT for NO_x, which was determined to be SNCR with ASOFA.^{2,3}

2.1.2 NO_x Emissions History

To determine the baseline emission rates, the time period of 2016-2018 was used. These results are shown in Table 3, along with the NO_x emissions for each year.

Table 3: Annual NO_x Rate and Emissions

Year	Emissions Rate (lb/MMBtu)	NO_x Emissions (tons)
2016	0.33	4,466
2017	0.33	6,390
2018	0.33	6,351
Average	0.33	5,736

¹ North Dakota State Implementation Plan for Regional Haze, March 3, 2010, p. 74.

² Available at: <https://www.epa.gov/enforcement/minnkota-power-cooperative-and-square-butte-electric-cooperative-settlement> (Last visited March 23, 2021)

³ North Dakota State Implementation Plan for Regional Haze, March 3, 2010, Appendix B.4, p.16-19.

The baseline was established in consultation with the NDDEQ. It is the most recent time period that includes two non-major outage years, and one major outage year. Outages on these units follow a three-year cycle, so the time period of 2016-2018 is the most representative of future expected emissions.⁴ The average emissions rate of 0.33 lb NO_x per MMBtu is used as the starting point when determining the cost of compliance for the add-on controls evaluated in Section 3.2.

2.2 SO₂

2.2.1 SO₂ Emissions Controls

MRYS Unit 2 is equipped with wet flue gas desulfurization (WFGD) for SO₂ control. This control technology was installed prior to the first round of the Regional Haze program. In the first round, the BART selected by the Department for Unit 2 was a 95% reduction efficiency or a limit of 0.15 lb/MMBtu on a 30-day rolling average, which could be achieved by modifying the existing scrubber. The Consent Decree for MRYS required a minimum of 90% reduction of SO₂ and was included in the BART permit.⁵ The WFGD system typically achieves an annual removal efficiency of approximately 95% and complies with a 30-day rolling average 90% SO₂ removal efficiency and a 30-day rolling average 0.15 lb/MMBtu emission rate.

2.2.2 SO₂ Emissions History

To determine the baseline emission rates, the time period of 2016-2018 was used. These results are shown in Table 4, along with the SO₂ emissions for each year.

Table 4: Annual SO₂ Emissions Rate

Year	Emissions Rate (lb/MMBtu)	SO₂ Emissions (tons)
2016	0.13	1,729
2017	0.13	2,507
2018	0.12	2,258
Average	0.13	2,165

The average emission rate of 0.13 lb SO₂ per MMBtu is representative of future expected operations and is used as the starting point when determining the cost of compliance for the additional controls evaluated in Section 4.2. Note that the tons of SO₂ listed in Table 4 do not equal the calculated tons used for the baseline emissions (Table 8). The baseline emissions are calculated using the recent emissions rate with the average ACF over the last 10 years. This results in a difference of approximately 30 tons of SO₂.

3 NO_x Four-Factor Analysis

3.1 NO_x Technologies

The reasonable progress controls evaluated by MRYS for Unit 2 are listed in Table 5. Performance rate and expected annual emissions are included for both control technologies that were determined to be technically feasible. MRYS evaluated optimizing their current SNCR control technologies as well as adding Rich Reagent Injection (RRI). Note that the expected annual emissions

⁴ Appendix B.5.b., p. 1-4. PDF page 1157.

⁵ North Dakota State Implementation Plan for Regional Haze, March 3, 2010, p. 71.

in Table 5 were calculated using the performance rate, potential heat input, and the ACF (Table 2). Therefore, the tons of NO_x emissions are different than the tons of NO_x emissions displayed in Table 3 since the table below contains calculated emissions based on representative operations.

Table 5: Reasonable Progress NO_x Controls

Control Technology	Performance Rate (lb/MMBtu)	Emissions (tons/year)
SNCR/ASOFA (baseline)	0.33	5,655
Optimized SNCR/ASOFA	0.32	5,418
RRI/SNCR/ASOFA	0.26	4,402

Selective catalytic reduction (SCR) was identified as a potential NO_x control technology but was deemed technically infeasible at MRYS in the previous BART and BACT analysis. No new information or experience has occurred since those analyses to change the conclusions that were made. SCR remains technically infeasible at MRYS.⁶

3.1.1 Optimization of Selective Non-Catalytic Reduction (SNCR)

Utilizing operating and vendor experience acquired since the original installation, enhancements to the existing system were identified to potentially reduce NO_x emission rates. Enhancements include changing the nozzles on existing lances, replacing the existing lances, adding lances in new locations and allowing for higher ammonia slip rates. Higher ammonia slip rates would allow for higher levels of urea injection, potentially reducing NO_x emission rates further. The ASOFA system would be operated in conjunction with the optimized SNCR system. These enhancements are projected to amount to approximately 240 tons of NO_x reductions per year. The optimization of SNCR was deemed technically feasible for Unit 2.

3.1.2 Rich Reagent Injection (RRI)

RRI is a NO_x emission control technology specifically intended for use on cyclone boilers. RRI adds dilute urea reagent to the hot boiler gases near the cyclones. This location must be devoid of free oxygen to avoid oxidation of the urea, which results in the formation of additional NO_x.⁷

The use of RRI control technology in conjunction with SNCR and ASOFA results in a 22% reduction in NO_x emissions from the baseline scenario. The expected performance rate would drop from 0.33 to 0.26 lb NO_x per MMBtu. The 0.26 lb per MMBtu performance rate was determined using MRYS unit-specific operations. Maximum NO_x reductions from both RRI and SNCR systems occur when the boiler is at or near full load, and in a steady-state condition. Emission rates stated by vendors are based on these conditions, and do not always account for site specific operating conditions. RRI's operational effectiveness depends on oxygen-deprived conditions. Both Unit 1 and Unit 2 at MRYS are designed to still be able to achieve full load even if one cyclone burner is out of service. This situation is not unusual during routine maintenance. When this occurs however, air can leak through

⁶ Appendix B.5.b., p. 2-3. PDF page 1163.

⁷ Appendix B.5.b., p. 2-3. PDF page 1163.

the combustion air dampers of an out-of-service cyclone and will result in the increase of NO_x formation, due to the addition of oxygen in the fuel-rich zone of the in-service boiler.⁸

Another problem MRYS encounters with RRI and other control technologies, is that MRYS is a mine-mouth plant that utilizes run-of-mine fuel. This results in significant coal quality variability. These variations can lead to cyclones becoming fouled, meaning that insufficient temperature exists for the slag to flow properly from the cyclone. When this occurs, fuel oil is co-burned in the fouled cyclone which results in increased oxygen levels in the fuel-rich zone. This leads to additional formation of NO_x.⁹ While these factors impact the performance rate for NO_x, the installation of RRI with SNCR and ASOFA was deemed technically feasible under limited conditions and will be evaluated further.

3.2 Step 1 – Cost of Compliance

The cost of compliance and incremental cost of compliance for the reasonable progress controls are listed in Table 6. Cost estimates are based on a vendor proposal and were calculated based on a 20-year project life.

Table 6: NO_x Cost of Compliance and Incremental Cost of Compliance

Control Technology	Performance Rate (lb/MMBtu)	Annual Emission Reduction (tpy)	Annualized Total Cost (\$)	Cost of Compliance (\$/ton)	Incremental Cost of Compliance (\$/ton)
SNCR/ASOFA (Baseline)	0.33				
Optimized SNCR/ASOFA	0.32	237	1,786,833	7,538	
RRI/SNCR/ASOFA	0.26	1,253	7,496,503	5,983	5,620

A detailed breakdown of the costs listed in Table 6 can be found in Minnkota's submitted four factor analysis.¹⁰ The Department has reviewed these costs and believes them to be accurate.

MRYS relied on a vendor proposal for cost estimates to account for certain site-specific costs that would be incurred implementing these NO_x control technologies. In the case of optimizing the SNCR, the detailed vendor evaluation identified new recommended SNCR injection locations, along with current nozzle and lance enhancements. The resulting annualized cost for Unit 2 is approximately \$1,800,000. These changes would result in an annual reduction of approximately 240 tons of NO_x, and a cost of compliance value of \$7,500 per ton of NO_x reduced.

The implementation of RRI with the SNCR and ASOFA systems would result in an approximate annual reduction of 1,250 tons of NO_x. The annualized total cost is approximately \$7,500,000, with a cost of compliance at \$6,000 per ton of NO_x reduced. MRYS submitted its original four-factor analysis on January 31, 2019. NDDEQ questioned the excessive cost estimates for RRI at that time. In the revised four-factor analysis that was submitted on May 29, 2019, MRYS defended these estimates. The cost estimates are site-specific and utilized computational fluid dynamic (CFD)

⁸ Appendix B.5.b, p. 2-5. PDF page 1165.

⁹ Appendix B.5.b, p. 2-5. PDF page 1165.

¹⁰ Appendix B.5.b. Appendix A. PDF page 1196 and 1211.

modeling and boiler mapping along with vendor proposals.¹¹ The CFD modeling, boiler mapping, and RRI injection analysis determined that the necessary injection locations needed are not in easily accessible locations on either unit. This results in added cost for new platforms and stairs to access new injection locations, significant new piping for increased urea, cooling water, dilution water and atomization air, expansion of the microfiltration and reverse osmosis water system, and supply and installation of the boiler bent tube openings for the new RRI and SNCR injectors.¹² Minnkota firmly believes that these costs are accurate and represent the actual costs for installation and implementation of RRI with SNCR and ASOFA.

3.3 Step 2 – Time Necessary for Compliance

The time necessary for compliance is not a limiting factor when determining additional reasonable controls for MRYS Unit 2 NO_x emissions since SNCR optimization and/or RRI could be installed prior to the end of the second planning period.

3.4 Step 3 – Energy and Non-Air Quality Environmental Impacts

3.4.1 Energy

The primary energy impact of utilizing RRI with SNCR or optimizing existing SNCR system is reduced boiler efficiency due to evaporation of large amounts of dilute urea. This results in excess coal needing to be burned to evaporate the expected amount of dilute urea in the boiler. An incremental increase in energy will also result from providing more compressed air for reagent atomization. Auxiliary power requirements result in a 66 kW increase in an optimized SNCR, and a 132 kW increase with RRI and SNCR.¹³ These energy impacts are only incrementally higher than the existing system, and do not remove either option from consideration.

3.4.2 Non-Air Quality Environmental Impacts

Non-air quality impacts of the control technologies are very similar to the impacts of the existing SNCR system. There may be an increase in ammonia slip, but a majority will be captured in the WFGD system. There will also be additional reverse osmosis/condensate waste due to the increase in demand from the systems and the need to dilute concentrated urea. This would result in millions of gallons of additional water treatment wastewaters being discharged from the MRYS facility on an annual basis. These impacts are considered acceptable and do not remove either option from consideration.

3.5 Step 4 – Remaining Useful Life

Based on the information provided to the Department, MRYS is expected to operate beyond the life of the control equipment. Therefore, remaining useful life was not considered.

¹¹ Appendix B.5.b., p. 2-4. PDF page 1164.

¹² Appendix B.5.b., p.2-7. PDF page 1167

¹³ Appendix B.5.b., p. 2-14. PDF page 1174.

4 SO₂ Four-Factor Analysis

4.1 SO₂ Technologies Evaluated

The reasonable progress controls that were identified for analysis for MRYS Unit 2 are listed in Table 7, along with their approximate annual control efficiency. All controls were deemed technically feasible.

Table 7: SO₂ Controls Identified for Analysis

Control Technology	Approximate Annual Control Efficiency
ReACT Scrubber	92-98%
New WFGD	98%
Modification of Existing WFGD	96-98%
Circulating Semi-Dry FGD	90-97%
Semi-Dry FGD	90-95%

As discussed in Section 2.2.1, the existing WFGD system currently achieves an annual average removal efficiency of approximately 95%. The approximate annual control efficiencies listed in Table 7 start from an estimate of uncontrolled SO₂ emissions based on inlet sulfur concentration.

4.1.1 Semi-Dry Flue Gas Desulfurization

Semi-dry FGD technology is an alternative to WFGD technology in SO₂ emission control. Spray Dryer Absorber (SDA) is the most common semi-dry FGD system. Circulating Dry Scrubber is another variation of the semi-dry process. SDA technology has never been clearly demonstrated to achieve the same SO₂ removal levels as WFGD technology.¹⁴ The CDS system can achieve better control efficiency than the SDA process, but only achieves similar levels to those of the current WFGD system. Because the semi-dry FGD technologies achieve less or equal SO₂ removal to that of the current WFGD system, neither was evaluated further.

4.1.2 Regenerative Activated Coke Technology

Regenerative Activated Coke Technology (ReACT) is a multipollutant control system that utilizes activated coke to remove SO₂, NO_x and mercury. The ReACT process has been demonstrated to achieve 99% SO₂ removal on low sulfur coal units. However, the supplier of the ReACT process determined that MRYS is not a good candidate for the technology. MRYS factors that would impact the performance and cost of ReACT are that the inlet temperature is too high, higher oxidation of the activated coke would be expected, and the sulfuric acid production rates would be very high.¹⁵ MRYS also utilizes high sulfur coal.¹⁶ ReACT has only been applied on low sulfur fuel, and pilot tests

¹⁴ Appendix B.5.b., p. 3-5. PDF page 1181.

¹⁵ Appendix B.5.b., p. 3-5. PDF page 1181.

¹⁶ Appendix B.5.b., p. 3-5. PDF page 1181.

on high sulfur coal have only shown 92-98% SO₂ removal rates. Because these levels could be achieved by the existing WFGD system, ReACT was not evaluated further.

4.1.3 Modification of Existing Wet FGD (WFGD) System

The original equipment manufacturer for the existing WFGD system on Unit 1 evaluated potential modifications that could increase the SO₂ removal efficiency of both systems. The upgrades that were evaluated include increasing the liquid-to-gas ratio, installation of new types of spray nozzles, running additional pumps, and adjusting the operating conditions of the scrubber. The evaluation determined that Unit 2 could achieve 97.6% SO₂ removal by increasing the Calcium/Sulfur stoichiometry to 1.020¹⁷ and replacing all of the absorber spray nozzles with dual flow nozzles.¹⁸ This modification was deemed technically feasible and was evaluated further.

4.1.4 New WFGD System

A new WFGD system was evaluated at a 98% SO₂ removal efficiency. While some new SO₂ control projects have achieved higher control efficiency, 98% was evaluated to account for upsets, fuel variability, and operation variability.¹⁹ A new WFGD system was deemed technically feasible for MRYS Unit 2. The performance rate and SO₂ annual emissions are shown for this technology, along with a modified WFGD and the baseline, in Table 8. Note that the expected annual emissions in Table 8 were calculated using the performance rate, potential heat input, and the ACF (Table 2). Therefore, the tons of SO₂ emissions are different than the tons of SO₂ emissions displayed in Table 4 since the table below contains calculated emissions based on representative operations.

Table 8: Reasonable Progress SO₂ Controls

Control Technology	Performance Rate (lb/MMBtu)	Emissions (tons/year)
WFGD (Baseline)	0.13	2,133
Modify WFGD	0.06	965
New WFGD	0.05	804

4.2 Step 1 – Cost of Compliance

The cost of compliance for reasonable progress SO₂ controls are shown in Table 9.

Table 9: SO₂ Cost of Compliance

Control Technology	Performance Rate (lb/MMBtu)	Annual Emission Reduction (tpy)	Annualized Total Cost (\$)	Cost of Compliance (\$/ton)	Incremental Cost (\$/ton)
WFGD (Baseline)	0.13				
Modify WFGD	0.06	1,168	839,319	718	
New WFGD	0.05	1,329	15,978,200	12,022	94,119

¹⁷ Appendix B.5.b., p. 3-4. PDF page 1180.

¹⁸ Appendix B.5.b., p.3-9. PDF page 1185.

¹⁹ Appendix B.5.b., p. 3-3. PDF page 1179.

A detailed breakdown of the costs listed in Table 9 can be found in Minnkota's submitted four factor analysis.²⁰ The Department has reviewed these costs and believes them to be accurate.

The cost estimates for modifying the existing WFGD system were provided by the original equipment manufacturer. These costs were supplemented with engineering estimates for installation from Burns & McDonnell. The cost estimates are limited to these factors and assumes that all other existing systems, including the existing electrical system, are capable of supporting the modifications with no further upgrades.²¹ It is also assumed that no change in operating staff will occur from the modifications. These conservative estimates result in a cost of compliance value of \$700 per ton of SO₂ removed.

The cost estimates for a new WFGD system were determined using the 'IPM Model – Updates to Cost and Performance for APC Technologies Wet FGD Cost Development Methodology' available from the U.S. Environmental Protection Agency and supplemented with engineering estimates based upon Burns & McDonnell's in-house experience.²² One option for the addition of a new WFGD would require new ductwork at the facility, modifications to the coal pile to create needed space, and electrical replacement/upgrades for the new scrubber. This option allows the new WFGD to be installed without an extended outage. The other option would require a significantly extended outage to allow for the existing WFGD system to be shut down while the new system was tied in, commissioned and started up.²³ A conservative approach was taken with the cost estimate of a new WFGD by assuming that all existing plant systems are capable of supporting the new system with no upgrades. The costs are representative of a typical furnish and erect contract by a WFGD system supplier. The resulting cost of compliance for a new WFGD system is approximately \$12,000, with an incremental cost of compliance of \$94,000.

4.3 Step 2 – Time Necessary for Compliance

The process to bid, design, purchase, and install retrofits to an existing WFGD system can take two to three years, with the installation of a new WFGD system taking significantly longer.²⁴ The time necessary for compliance is not a limiting factor when determining additional reasonable controls for MRYS Unit 2 since all reasonable cost effective SO₂ control technologies could be installed prior to the end of the second planning period.

4.4 Step 3 – Energy and Non-Air Quality Environmental Impacts

4.4.1 Energy

Modifying the existing WFGD will result in an energy demand increase of 965 kW, a 0.2% increase in the percent of nominal generation. A new WFGD will result in an increase of 2,195 kW, a 0.5%

²⁰ Appendix B.5.b., p.3-9 – 3-13. PDF page 1185-1189.

²¹ Appendix B.5.b., p. 3-9. PDF page 1185.

²² Appendix B.5.b., p. 3-7. PDF page 1183.

²³ Appendix B.5.b., p. 3-8. PDF page 1184.

²⁴ Appendix B.5.b., p. 3-14. PDF page 1190.

increase in the percent of nominal generation.²⁵ These increases are acceptable and do not remove these as control options.

4.4.2 Non-Air Quality Environmental Impacts

Modifying the existing WFGD system will have similar non-air quality environmental impacts to those of the existing system. However, there will be an incremental increase in the solids disposal rate as additional removal of SO₂ will result in increased byproduct. This is not a significant impact and does not remove the control technology from consideration.

4.5 Step 4 – Remaining Useful Life

Based on the information provided to the Department, MRYS is expected to operate beyond the life of the control equipment. Therefore, remaining useful life was not considered.

Re: Acid Rain Program Retired Unit Exemption Notice
Montana-Dakota Utilities
R.M. Heskett Station Unit 2 (Coal-fired)

Dear Mr. Semerad:

On behalf of Montana-Dakota Utilities (Montana-Dakota), please allow the following correspondence and attached form to serve as Montana-Dakota's timely and formal Retired Unit Exemption Notice. As of January 31, 2022, R.M. Heskett Station Unit 2 will be permanently retired. As such, Unit 2 qualifies for the retired unit exemption pursuant to Title 40 of the Code of Federal Regulations (CFR), Part 72 (40 CFR 72.8).

A signed Retired Unit Exemption form (EPA Form 7610-20) is attached. Montana-Dakota will maintain records demonstrating R.M. Heskett Station Unit 2 is permanently retired for a period of five (5) years, as required by 40 CFR 72.8(d)(5). We would also like to formally inform you the smaller, older 25 MW R.M. Heskett Unit 1 (coal-fired) was permanently shut down (and did not operate) beginning February 25, 2022. Both units are undergoing decommissioning now and anticipated demolition starting late this year. Thank you for your time and attention to this filing.

Should additional information or detail be necessary, please feel free to contact Mark Dihle at 701.222.7865 or mark.dihle@mdu.com

Respectfully submitted,

Mark Dihle
Sr. Environmental Specialist

Andy McDonald, Environmental Compliance Manager

Retired Unit Exemption

For more information, see instructions and refer to 40 CFR 72.8, 97.405, 97.505, 97.605, 97.705, 97.805, 97.905, 97.1005 or a comparable state regulation, as applicable.

This submission is: ☒ New ☐ Revised

STEP 1

Identify the unit by plant (source) name, State, plant code and unit ID#.

Plant (Source) Name R.M. Heskett Station	State ND	Plant Code 2790	Unit ID# B2
---	-------------	--------------------	----------------

STEP 2

Indicate the program(s) that the unit is subject to.

- | | |
|---|--|
| <input checked="" type="checkbox"/> Acid Rain | <input type="checkbox"/> CSAPR SO ₂ Group 1 |
| <input type="checkbox"/> CSAPR NO _x Annual | <input type="checkbox"/> CSAPR SO ₂ Group 2 |
| <input type="checkbox"/> CSAPR NO _x Ozone Season Group 1 | <input type="checkbox"/> Texas SO ₂ |
| <input type="checkbox"/> CSAPR NO _x Ozone Season Group 2 | |
| <input type="checkbox"/> CSAPR NO _x Ozone Season Group 3 | |

STEP 3

Identify the date on which the unit was (or will be) permanently retired.

01/31/2022

STEP 4

If the unit is subject to the Acid Rain Program, identify the first full calendar year in which the unit meets (or will meet) the requirements of 40 CFR 72.8(d).

Calendar year starting January 1, 2023
--

STEP 5 Read the applicable special provisions.

Acid Rain Program Special Provisions

(1) A unit exempt under 40 CFR 72.8 shall not emit any sulfur dioxide and nitrogen oxides starting on the date that the exemption takes effect. The owners and operators of the unit will be allocated allowances in accordance with 40 CFR part 73 subpart B.

(2) A unit exempt under 40 CFR 72.8 shall not resume operation unless the designated representative of the source that includes the unit submits a complete Acid Rain permit application under 40 CFR 72.31 for the unit not less than 24 months prior to the date on which the unit is first to resume operation.

(3) The owners and operators and, to the extent applicable, the designated representative of a unit exempt under 40 CFR 72.8 shall comply with the requirements of the Acid Rain Program concerning all periods for which the exemption is not in effect, even if such requirements arise, or must be complied with, after the exemption takes effect.

(4) For any period for which a unit is exempt under 40 CFR 72.8, the unit is not an affected unit under the Acid Rain Program and 40 CFR parts 70 and 71 and is not eligible to be an opt-in source under 40 CFR part 74. As an unaffected unit, the unit shall continue to be subject to any other applicable requirements under 40 CFR parts 70 and 71.

(5) For a period of 5 years from the date the records are created, the owners and operators of a unit exempt under 40 CFR 72.8 shall retain, at the source that includes the unit, records demonstrating that the unit is permanently retired. The 5-year period for keeping records may be extended for cause, at any time prior to the end of the period, in writing by the Administrator or the permitting authority. The owners and operators bear the burden of proof that the unit is permanently retired.

(6) On the earlier of the following dates, a unit exempt under 40 CFR 72.8(b) or (c) shall lose its exemption and become an affected unit under the Acid Rain Program and 40 CFR parts 70 and 71: (i) the date on which the designated representative submits an Acid Rain permit application under paragraph (2); or (ii) the date on which the designated representative is required under paragraph (2) to submit an Acid Rain permit application. For the purpose of applying monitoring requirements under 40 CFR part 75, a unit that loses its exemption under 40 CFR 72.8 shall be treated as a new unit that commenced commercial operation on the first date on which the unit resumes operation.

CSAPR NO_x Annual Trading Program Special Provisions

(1) A unit exempt under 40 CFR 97.405 shall not emit any NO_x, starting on the date that the exemption takes effect.

(2) For a period of 5 years from the date the records are created, the owners and operators of a unit exempt under 40 CFR 97.405 shall retain, at the source that includes the unit, records demonstrating that the unit is permanently retired. The 5-year period for keeping records may be extended for cause, at any time before the end of the period, in writing by the Administrator. The owners and operators bear the burden of proof that the unit is permanently retired.

(3) The owners and operators and, to the extent applicable, the designated representative of a unit exempt under 40 CFR 97.405 shall comply with the requirements of the CSAPR NO_x Annual Trading Program concerning all periods for which the exemption is not in effect, even if such requirements arise, or must be complied with, after the exemption takes effect.

(4) A unit exempt under 40 CFR 97.405 shall lose its exemption on the first date on which the unit resumes operation. Such unit shall be treated, for purposes of applying allocation, monitoring, reporting, and recordkeeping requirements under 40 CFR part 97 subpart AAAAA, as a unit that commences commercial operation on the first date on which the unit resumes operation.

CSAPR NO_x Ozone Season Group 1 Trading Program Special Provisions

(1) A unit exempt under 40 CFR 97.505 shall not emit any NO_x, starting on the date that the exemption takes effect.

(2) For a period of 5 years from the date the records are created, the owners and operators of a unit exempt under 40 CFR 97.505 shall retain, at the source that includes the unit, records demonstrating that the unit is permanently retired. The 5-year period for keeping records may be extended for cause, at any time before the end of the period, in writing by the Administrator. The owners and operators bear the burden of proof that the unit is permanently retired.

(3) The owners and operators and, to the extent applicable, the designated representative of a unit exempt under 40 CFR 97.505 shall comply with the requirements of the CSAPR NO_x Ozone Season Group 1 Trading Program concerning all periods for which the exemption is not in effect, even if such requirements arise, or must be complied with, after the exemption takes effect.

(4) A unit exempt under 40 CFR 97.505 shall lose its exemption on the first date on which the unit resumes operation. Such unit shall be treated, for purposes of applying allocation, monitoring, reporting, and recordkeeping requirements under 40 CFR part 97 subpart BBBB, as a unit that commences commercial operation on the first date on which the unit resumes operation.

CSAPR NO_x Ozone Season Group 2 Trading Program Special Provisions

(1) A unit exempt under 40 CFR 97.805 shall not emit any NO_x, starting on the date that the exemption takes effect.

(2) For a period of 5 years from the date the records are created, the owners and operators of a unit exempt under 40 CFR 97.805 shall retain, at the source that includes the unit, records demonstrating that the unit is permanently retired. The 5-year period for keeping records may be extended for cause, at any time before the end of the period, in writing by the Administrator. The owners and operators bear the burden of proof that the unit is permanently retired.

(3) The owners and operators and, to the extent applicable, the designated representative of a unit exempt under 40 CFR 97.805 shall comply with the requirements of the CSAPR NO_x Ozone Season Group 2 Trading Program concerning all periods for which the exemption is not in effect, even if such requirements arise, or must be complied with, after the exemption takes effect.

(4) A unit exempt under 40 CFR 97.805 shall lose its exemption on the first date on which the unit resumes operation. Such unit shall be treated, for purposes of applying allocation, monitoring, reporting, and recordkeeping requirements under 40 CFR part 97 subpart EEEEE, as a unit that commences commercial operation on the first date on which the unit resumes operation.

CSAPR NO_x Ozone Season Group 3 Trading Program Special Provisions

(1) A unit exempt under 40 CFR 97.1005 shall not emit any NO_x, starting on the date that the exemption takes effect.

(2) For a period of 5 years from the date the records are created, the owners and operators of a unit exempt under 40 CFR 97.1005 shall retain, at the source that includes the unit, records demonstrating that the unit is permanently retired. The 5-year period for keeping records may be extended for cause, at any time before the end of the period, in writing by the Administrator. The owners and operators bear the burden of proof that the unit is permanently retired.

(3) The owners and operators and, to the extent applicable, the designated representative of a unit exempt under 40 CFR 97.1005 shall comply with the requirements of the CSAPR NO_x Ozone Season Group 3 Trading Program concerning all periods for which the exemption is not in effect, even if such requirements arise, or must be complied with, after the exemption takes effect.

(4) A unit exempt under 40 CFR 97.1005 shall lose its exemption on the first date on which the unit resumes operation. Such unit shall be treated, for purposes of applying allocation, monitoring, reporting, and recordkeeping requirements under this subpart, as a unit that commences commercial operation on the first date on which the unit resumes operation.

CSAPR SO₂ Group 1 Trading Program Special Provisions

(1) A unit exempt under 40 CFR 97.605 shall not emit any SO₂, starting on the date that the exemption takes effect.

(2) For a period of 5 years from the date the records are created, the owners and operators of a unit exempt under 40 CFR 97.605 shall retain, at the source that includes the unit, records demonstrating that the unit is permanently retired. The 5-year period for keeping records may be extended for cause, at any time before the end of the period, in writing by the Administrator. The owners and operators bear the burden of proof that the unit is permanently retired.

(3) The owners and operators and, to the extent applicable, the designated representative of a unit exempt under 40 CFR 97.605 shall comply with the requirements of the CSAPR SO₂ Group 1 Trading Program concerning all periods for which the exemption is not in effect, even if such requirements arise, or must be complied with, after the exemption takes effect.

(4) A unit exempt under 40 CFR 97.605 shall lose its exemption on the first date on which the unit resumes operation. Such unit shall be treated, for purposes of applying allocation, monitoring, reporting, and recordkeeping requirements under 40 CFR part 97 subpart CCCCC, as a unit that commences commercial operation on the first date on which the unit resumes operation.

CSAPR SO₂ Group 2 Trading Program Special Provisions

(1) A unit exempt under 40 CFR 97.705 shall not emit any SO₂, starting on the date that the exemption takes effect.

(2) For a period of 5 years from the date the records are created, the owners and operators of a unit exempt under 40 CFR 97.705 shall retain, at the source that includes the unit, records demonstrating that the unit is permanently retired. The 5-year period for keeping records may be extended for cause, at any time before the end of the period, in writing by the Administrator. The owners and operators bear the burden of proof that the unit is permanently retired.

(3) The owners and operators and, to the extent applicable, the designated representative of a unit exempt under 40 CFR 97.705 shall comply with the requirements of the CSAPR SO₂ Group 2 Trading Program concerning all periods for which the exemption is not in effect, even if such requirements arise, or must be complied with, after the exemption takes effect.

(4) A unit exempt under 40 CFR 97.705 shall lose its exemption on the first date on which the unit resumes operation. Such unit shall be treated, for purposes of applying allocation, monitoring, reporting, and recordkeeping requirements under 40 CFR part 97 subpart DDDDD, as a unit that commences commercial operation on the first date on which the unit resumes operation.

Texas SO₂ Trading Program Special Provisions

- (1) A unit exempt under 40 CFR 97.905 shall not emit any SO₂, starting on the date that the exemption takes effect.
- (2) For a period of 5 years from the date the records are created, the owners and operators of a unit exempt under 40 CFR 97.905 shall retain, at the source that includes the unit, records demonstrating that the unit is permanently retired. The 5-year period for keeping records may be extended for cause, at any time before the end of the period, in writing by the Administrator. The owners and operators bear the burden of proof that the unit is permanently retired.
- (3) The owners and operators and, to the extent applicable, the designated representative of a unit exempt under 40 CFR 97.905 shall comply with the requirements of the Texas SO₂ Trading Program concerning all periods for which the exemption is not in effect, even if such requirements arise, or must be complied with, after the exemption takes effect.
- (4) A unit exempt under 40 CFR 97.905 shall lose its exemption on the first date on which the unit resumes operation. A retired unit that resumes operation will not receive an allowance allocation under 40 CFR 97.911. The unit may receive allowances from the Supplemental Allowance Pool pursuant to 40 CFR 97.912. All other provisions of 40 CFR part 97 subpart FFFFF regarding monitoring, reporting, recordkeeping and compliance will apply on the first date on which the unit resumes operation.

STEP 6 Read the statement of compliance and the applicable certification statements, sign, and date.

Statement of compliance

I certify that the unit identified above at STEP 1 was (or will be) permanently retired on the date identified at STEP 3 and will comply with the applicable Special Provisions listed at STEP 5.

Certification by designated representatives or alternate designated representatives

I am authorized to make this submission on behalf of the owners and operators of the source and unit for which the submission is made. I certify under penalty of law that I have personally examined, and am familiar with, the statements and information submitted in this document and all its attachments. Based on my inquiry of those individuals with primary responsibility for obtaining the information, I certify that the statements and information are to the best of my knowledge and belief true, accurate, and complete. I am aware that there are significant penalties for submitting false statements and information or omitting required statements and information, including the possibility of fine or imprisonment.

Signature		Date	3/7/2023

Certification by certifying officials of units subject only to the Acid Rain Program for which no designated representative has been authorized

I certify under penalty of law that I have personally examined, and am familiar with, the statements and information submitted in this document and all its attachments. Based on my inquiry of those individuals with primary responsibility for obtaining the information, I certify that the statements and information are to the best of my knowledge and belief true, accurate, and complete. I am aware that there are significant penalties for submitting false statements and information or omitting required statements and information, including the possibility of fine or imprisonment.

Name	NA	Title	
Owner Company Name			
Email		Phone	
Signature	NA	Date	

Instructions for the Retired Unit Exemption Notice

Please type or print. If you have any questions regarding the submission of the Retired Unit Exemption notice, please send an email to CAMDForms@epa.gov, or contact your local, State, or EPA Regional contact for the Acid Rain Program (ARP), Cross-State Air Pollution Rule (CSAPR), or TexasSO₂ Trading Program (TXSO₂), as appropriate. You may also call EPA's Acid Rain Hotline at (202) 343- 9620.

Submission Deadline: For units subject only to the ARP, submit the Retired Unit Exemption notice by December 31 of the first year the unit is to be exempt. For units subject to the CSAPR or TXSO₂ programs (including units also subject to the ARP), submit the Retired Unit Exemption notice no later than 30 days after the date the unit is permanently retired (i.e., within 30 days of the date entered at STEP 3).

STEP 1 Enter the plant name and state where the unit is located, the Plant Code for the facility, and the Unit ID for the unit, consistent with the data listed on the most current Certificate of Representation for the facility. A Plant Code is a number assigned by the Department of Energy's (DOE) Energy Information Administration (EIA) to facilities that generate electricity. For older facilities, "Plant Code" is synonymous with "ORISPL" and "Facility" codes. If the facility generates electricity but no Plant Code has been assigned, or if there is uncertainty regarding what the Plant Code is, contact EIA at (202) 586-1029. For facilities that do not produce electricity, use the facility identifier assigned by EPA (beginning with "88"). If the facility does not produce electricity and has not been assigned a facility identifier, please send an email to CAMDForms@epa.gov.

STEP 2 Identify the programs to which the unit is subject.

STEP 3 Enter the date on which the unit was (or will be) permanently retired.

STEP 4 If the unit is subject to the ARP, identify the first full calendar year in which the unit meets (or will meet) the requirements of 40 CFR 72.8(d).

STEP 5 Read the applicable special provisions.

STEP 6 Read the statement of compliance and the applicable certification statements, sign, and date. For units subject only to the ARP, if no designated representative has been authorized, a certifying official for each owner of the unit must read the certification at STEP 6 labeled "certifying officials of units subject only to the Acid Rain Program", enter his or her name, title, name of the owner company for which he or she is the certifying official, phone number, email address, and then sign and date. A certifying official is not required to submit a Certificate of Representation. If there is more than one owner of a unit for which no designated representative has been authorized, each owner of the unit must have a certifying official sign the appropriate certification at STEP 6.

Submit the original Retired Unit Exemption notice to the title V permitting authority for the facility, and mail a copy to one of the following mailing addresses (**please note the different zip codes**):

For Regular or Certified Mail:

Paperwork Burden Estimate

This collection of information is approved by OMB under the Paperwork Reduction Act, 44 U.S.C. 3501 et seq. (OMB Control Nos. 2060-0258 and 2060-0667). Responses to this collection of information are mandatory (40 CFR 72.8, 97.405, 97.505, 97.605, 97.705, 97.805, 97.905 and 97.1005). An agency may not conduct or sponsor, and a person is not required to respond to, a collection of information unless it displays a currently valid OMB control number. The public reporting and recordkeeping burden for this collection of information is estimated to be 3.5 hours per response annually. Send comments on the Agency's need for this information, the accuracy of the provided burden estimates and any suggested methods for minimizing respondent burden to the Regulatory Support Division Director, U.S. Environmental Protection Agency (2821T), 1200 Pennsylvania Ave., NW, Washington, D.C. 20460. Include the OMB control number in any correspondence. Do not send the completed form to this address.

February 16, 2021

Mr. Jay Skabo
Vice President – Electric Supply
Montana-Dakota Utilities Co.

Bismarck, ND 58501

Re: Air Pollution Control
Permit to Construct

Dear Mr. Skabo:

Pursuant to the Air Pollution Control Rules of the State of North Dakota, the Department of Environmental Quality (Department) has reviewed the application dated April 30, 2020 (updated January 11, 2021) to obtain a Permit to Construct for the removal of two existing coal-fired boilers and ancillary equipment as well as the installation of a new, 88 megawatt natural gas-fired simple cycle combustion turbine unit at the R.M. Heskett Station located in Morton County, ND.

Based on the results of the documents submitted on April 30, 2020 (updated January 11, 2021) the Department hereby issues the enclosed North Dakota Air Pollution Control Permit to Construct No. ACP-17983.v1.0.

Please advise the Department within 15 days after completing the project to allow for an inspection by the Department.

Note that the above-referenced permit addresses only air quality requirements applicable to your facility. Other divisions (Water Quality, Waste Management and Municipal Facilities) within the Department of Environmental Quality may have additional requirements. Contact information for the various divisions is listed at the bottom of this letter.

Please contact me at (701)328-5283 or at cristy.jones@nd.gov with any questions.

Sincerely,

Cristy Jones
Environmental Scientist
Division of Air Quality

CMJ:csc

**AIR POLLUTION CONTROL
PERMIT TO CONSTRUCT**

Pursuant to Chapter 23.1-06 of the North Dakota Century Code, and the Air Pollution Control Rules of the State of North Dakota (Article 33.1-15 of the North Dakota Administrative Code), and in reliance on statements and representations heretofore made by the owner designated below, a Permit to Construct is hereby issued authorizing such owner to construct and initially operate the source unit(s) at the location designated below. This Permit to Construct is subject to all applicable rules and orders now or hereafter in effect of the North Dakota Department of Environmental Quality (Department) and to any conditions specified below:

I. General Information:

A. **Permit to Construct Number:** ACP-17983 v1.0

B. **Source:**

1. Name: Montana-Dakota Utilities Co.
2. Location: R. M. Heskett Station
2025-38th Street
Mandan, ND 58554
Morton County
3. Source Type: , Electric Generating Unit; Simple Cycle Combustion Turbine
4. Existing Equipment at the Facility:

Emission Unit Description	Emission Unit (EU)	Emission Point (EP)	Air Pollution Control Equipment
Coal-fired boiler with a rated heat input of 387.63×10^6 Btu/hr (Unit 1 boiler)	1	1	Electrostatic Precipitator (ESP)
Coal-fired boiler with a rated heat input of 916.5×10^6 Btu/hr (Unit 2 boiler)	2	2	Multiclone, ESP and Limestone addition to bed media (limestone addition operates on an as-needed basis)
Natural gas-fired IC engine rated at 134 bhp, 100 kW output, built 1963 (Emergency generator engine)	3	3	None

Emission Unit Description	Emission Unit (EU)	Emission Point (EP)	Air Pollution Control Equipment
Natural gas-fired sand dryer with a rated heat input of 3.0×10^6 Btu/hr (Sand dryer)	5	2	ESP (Emissions from EU 5 discharge into the inlet of the Unit 2 ESP)
Natural gas-fired combustion turbine nominally rated at 986×10^6 Btu/hr, built 2013 (Unit 3 turbine)	6	6	Dry Low NO _x (DLN) Combustion
Natural gas-fired in-line heater nominally rated at 2.75×10^6 Btu/hr (Unit 3 in-line heater)	7	7	None
Unit 1 coal storage silo	M1	M1	Fabric Filter
Unit 1 coal gallery	M2	M1	Fabric Filter
Three Unit 2 coal storage silos	2A, 2B & 2C	M3	Fabric Filters
Ash conveyor system	M4	M4	Fabric Filter
Unit 1 bottom ash silo	M5	M5	Fabric Filter
Sand storage silos	S2B	M6	Fabric Filter
Limestone hopper	S2A	M6	Fabric Filter
Fly ash silo	M7	M7	Fabric Filters
Gasoline storage tank, 1000 gal, built Dec. 2006	M8 ^B	M8	Submerged fill pipe
Limestone silo and limestone receiving	M9	M9	Fabric Filter
Limestone conveyor	M11	M11	Fabric Filters
Fugitive emissions	FUG	FUG	None

5. Equipment to be removed:

Emission Unit Description ^A	Emission Unit (EU)	Emission Point (EP)	Air Pollution Control Equipment
Coal-fired boiler with a rated heat input of 387.63×10^6 Btu/hr (Unit 1 boiler)	1	1	Electrostatic Precipitator (ESP)
Coal-fired boiler with a rated heat input of 916.5×10^6 Btu/hr (Unit 2 boiler)	2	2	Multiclone, ESP and Limestone addition to bed media
Natural gas-fired IC engine rated at 134 bhp, 100 kW output, built 1963 (Emergency generator engine)	3	3	None

Natural gas-fired sand dryer with a rated heat input of 3.0×10^6 Btu/hr (Sand dryer)	5	2	ESP
Unit 1 coal storage silo	M1	M1	Fabric Filter
Unit 1 coal gallery	M2	M1	Fabric Filter
Three Unit 2 coal storage silos	2A, 2B & 2C	M3	Fabric Filters
Ash conveyor system	M4	M4	Fabric Filter
Unit 1 bottom ash silo	M5	M5	Fabric Filter
Sand storage silos	S2B	M6	Fabric Filter
Limestone hopper	S2A	M6	Fabric Filter
Fly ash silo	M7	M7	Fabric Filters
Gasoline storage tank, 1000 gal, built Dec. 2006	M8	M8	Submerged fill pipe
Limestone silo and limestone receiving	M9	M9	Fabric Filter
Limestone conveyor	M11	M11	Fabric Filters

^A Emission units must be removed or permanently decommissioned prior to the commencement of operation of the Unit 4 turbine (EU 12).

6. New equipment to be added to the facility:

Emission Unit Description	Emission Unit (EU)	Emission Point (EP)	Air Pollution Control Equipment
Natural gas-fired combustion turbine nominally rated at 986×10^6 Btu/hr (Unit 4 turbine) (KKKK) (TTTT)	12 ^A	12	Dry Low NO _x (DLN) Combustion
Natural gas-fired in-line heater nominally rated at 5×10^6 Btu/hr (Unit 4 in-line heater)	13	13	None
One (4SLB) natural gas-fired emergency generator rated at 5,364 bhp (2020 or newer) (JJJJ) (ZZZZ)	14 ^A	14	None

^A The potential to emit for an emergency stationary reciprocating internal combustion engine (RICE) is based on operating no more hours per year than is allowed by the subparts (40 CFR 60, Subpart JJJJ and 40 CFR 63, Subpart ZZZZ) for other than emergency situations. For engines to be considered emergency stationary RICE under the RICE rules, engine operations must comply with the operating hour limits as specified in the applicable subparts. There is no time limit on the use of emergency stationary RICE in emergency situations.

C. **Owner/Operator (Permit Applicant):**

1. Name: Montana-Dakota Utilities Co.
2. Address: 400 N Fourth Street
Bismarck, ND 58501
3. Application Date: April 30, 2020

II. **Conditions:** This Permit to Construct allows the construction and initial operation of the above-mentioned new or modified equipment at the source. The source may be operated under this Permit to Construct until a Permit to Operate is issued unless this permit is suspended or revoked. The source is subject to all applicable rules, regulations, and orders now or hereafter in effect of the North Dakota Department of Environmental Quality and to the conditions specified below.

A. **Emission Limits:** Emission limits from the operation of the source unit(s) identified in Item I.B of this Permit to Construct (hereafter referred to as "permit") are as follows. Source units not listed are subject to the applicable emission limits specified in the North Dakota Air Pollution Control Rules.

Emission Unit Description	EU	EP	Pollutant / Parameter	Emission Limit
Natural gas-fired combustion turbine nominally rated at 986×10^6 Btu/hr (Unit 4 turbine)	12	12	NO _x : >50 MW (gross) & >0°F	15 ppmvd @ 15% O ₂ or 54 ng/J (0.43 lb/MWh) ^{A, B, C, D}
			NO _x : ≤50 MW (gross) or <0°F	96 ppmvd @ 15% O ₂ or 590 ng/J (4.7 lb/MWh) ^{A, B, C, D}
			NO _x	515.8 lb/hr ^I
			SO ₂	110 ng/J (0.90 lb/MWh) (gross) or 0.060 lb/MMBtu (fuel use) ^E
			CO ₂	50 kg CO ₂ /GJ heat input (120 lb CO ₂ /MMBtu) ^{F, G}
			Opacity	20% ^H

^A CEMs installed in lieu of annual performance tests (40 CFR 60.4340(b)).

^B CEMs installation, operation, and performance testing must meet the applicable standards of 40 CFR 60 Subpart KKKK.

^C Based on a 4-hr rolling average.

^D The higher NO_x limit emission limit applies for the entire hour if at any point in the hour the unit was subject to a higher limit.

- E Sulfur content of the fuel must be determined using total sulfur methods per 40 CFR 60.4415 and 60.4370.
- F Emissions standards must be met at all times; however, compliance must be determined only at the end of each applicable operating month.
- G Emission limit is based on operations that supply less than or equal to its design efficiency (33.34%) or 50%, whichever is less, times its potential electric output as net-electric sales on either a 12-operating month or a 3-year rolling average basis and combusts > 90% natural gas.
- H 40% permissible for not more than one six-minute period per hour.
- I Based on a 1-hr average.

B. Fuel Restriction:

The simple cycle combustion turbines, in-line heater, and emergency generator (EUs 12, 13, and 14) are restricted to combusting only natural gas containing no more than 2 grains of sulfur per 100 standard cubic feet.

C. Emissions Testing:

1. Initial Testing: Within 180 days after initial startup, the permittee shall conduct emissions tests at the emission units listed below using an independent testing firm, to determine the compliance status of the facility with respect to the emission limits specified in Condition II.A. Emissions testing shall be conducted for the pollutant(s) listed below in accordance with EPA Reference Methods listed in 40 CFR 60, Appendix A. Test methods other than those listed below may be used upon approval by the Department.

Emission Unit Description	EU	Pollutant/Parameter	Number of Runs	Length of Runs	EPA Ref. Method(s)
Unit 4 turbine	12	NO _x CEMS Relative Accuracy Test Audit (RATA)	9	21 min	See 40 CFR 60.4405 for alternative method

A RATA must be conducted at a single load level, within plus or minus 25% of 100% of peak load and the ambient temperature must be greater than 0°F during the RATA runs.

A signed copy of the test results shall be furnished to the Department within 60 days of the test date. The basis for this condition is NDAC 33.1-15-01-12 which is hereby incorporated into this permit by reference. To facilitate preparing for and conducting such tests, and to facilitate reporting the test results to the Department, the owner/operator shall follow the procedures and formats in the Department's Emission Testing Guideline.

2. Notification: The permittee shall notify the Department using the form in the Emission Testing Guideline, or its equivalent, at least 30 calendar days in advance of any tests of emissions of air contaminants required by the Department. If the permittee is unable to conduct the performance test on the scheduled date, the permittee shall notify the Department at least five days prior to the scheduled test date and coordinate a new test date with the Department.
3. Sampling Ports/Access: Sampling ports shall be provided downstream of all emission control devices and in a flue, conduit, duct, stack or chimney arranged to conduct emissions to the ambient air.

The ports shall be located to allow for reliable sampling and shall be adequate for test methods applicable to the facility. Safe sampling platforms and safe access to the platforms shall be provided. Plans and specifications showing the size and location of the ports, platform and utilities shall be submitted to the Department for review and approval.

4. Other Testing:
 - a) The Department may require the permittee to have tests conducted to determine the emission of air contaminants from any source, whenever the Department has reason to believe that an emission of a contaminant not addressed by the permit applicant is occurring, or the emission of a contaminant in excess of that allowed by this permit is occurring. The Department may specify testing methods to be used in accordance with good professional practice. The Department may observe the testing. All tests shall be conducted by reputable, qualified personnel. A signed copy of the test results shall be furnished to the Department within 60 days of the test date.

All tests shall be made and the results calculated in accordance with test procedures approved by the Department. All tests shall be made under the direction of persons qualified by training or experience in the field of air pollution control as approved by the Department.
 - b) The Department may conduct tests of emissions of air contaminants from any source. Upon request of the Department, the permittee shall provide necessary holes in stacks or ducts and such other safe and proper sampling and testing facilities, exclusive of instruments and sensing devices, as may be necessary for proper determination of the emission of air contaminants.

D. **Stack Heights**: The stack height of the turbine shall be at least 56 feet.

- E. **New Source Performance Standards (NSPS):** The owner/operator shall comply with all applicable requirements of the following NSPS subparts as referenced in Chapter 33.1-15-12 of the North Dakota Air Pollution Control Rules and 40 CFR 60.
1. **40 CFR 60, Subpart KKKK:** The owner/operator shall comply with all applicable requirements of 40 CFR 60, Subpart KKKK – Standards of Performance for Stationary Combustion Turbines (EU 12).
 2. **40 CFR 60, Subpart JJJJ:** The owner/operator shall comply with all applicable requirements of 40 CFR 60, Subpart JJJJ – Standards of Performance for Stationary Spark Ignition Internal Combustion Engines (EU 14).
 3. **40 CFR 60, Subpart TTTT:** The owner/operator shall comply with all applicable requirements of 40 CFR 60, Subpart TTTT - Standards of Performance for Greenhouse Gas Emissions for Electric Generating Units (EU 12).
- F. **Maximum Achievable Control Technology Standards (MACT):** The permittee shall comply with all applicable requirements of the following MACT subparts as referenced in Chapter 33.1-15-22 of the North Dakota Air Pollution Control Rules and 40 CFR 63.
1. 40 CFR 63, Subpart ZZZZ - National Emissions Standards for Hazardous Air Pollutants for Stationary Reciprocating Internal Combustion Engines (EU 1). The North Dakota Department of Environmental Quality has not adopted the area source provisions of this subpart. All required documentation must be submitted to EPA Region 8 at the following address:

U.S. EPA Region 8
1595 Wynkoop Street
Mail Code 8ENF – AT
Denver, CO 80202-1129
- G. **Like-Kind Turbine Replacement:** This permit allows the permittee to replace the turbine with a like-kind turbine. Replacement is subject to the following conditions.
1. The Department must be notified within 10 days after change-out of the turbine.
 2. The replacement turbine shall operate in the same manner, provide no increase in throughput and have equal or less emissions than the turbine it is replacing.

3. The date of manufacture of the replacement turbine must be included in the notification. The facility must comply with any applicable federal standards (e.g. NSPS, NESHAP, MACT) triggered by the replacement.
 4. The replacement turbine is subject to the same state emission limits as the existing turbine in addition to any NSPS or MACT emission limit that is applicable. Testing shall be conducted to confirm compliance with the emission limits within 180 days after start-up of the new turbine.
- H. **CEMS –Nitrogen Oxide (NO_x):** The owner/operator shall install, operate, calibrate and maintain an instrument for continuously monitoring and recording the concentration by volume (dry basis, 0 percent excess air) of NO_x emissions into the atmosphere. The monitor must include an O₂ monitor for correcting the data for excess air. Monitoring of NO_x emissions must also meet all applicable requirements of 40 CFR 60, Subpart KKKK.
- I. **Construction:** Construction of the above described facility shall be in accordance with information provided in the permit application as well as any plans, specifications and supporting data submitted to the Department. The Department shall be notified ten days in advance of any significant deviations from the specifications furnished. The issuance of this Permit to Construct may be suspended or revoked if the Department determines that a significant deviation from the plans and specifications furnished has been or is to be made.
- Any violation of a condition issued as part of this permit to construct as well as any construction which proceeds in variance with any information submitted in the application, is regarded as a violation of construction authority and is subject to enforcement action.
- J. **Startup Notice:** A notification of the actual date of initial startup shall be submitted to the Department within 15 days after the date of initial startup.
- K. **Organic Compounds Emissions:** The permittee shall comply with all applicable requirements of NDAC 33.1-15-07 – Control of Organic Compounds Emissions.
- L. **Title V Permit to Operate:** Within one year after startup of the units covered by this Permit to Construct, the owner/operator shall submit a permit application to modify the existing Title V Permit to Operate for the facility.
- M. **Acid Rain Program:** The permittee shall comply with the applicable requirements of 40 CFR 72, 75 and 76. The permittee shall hold sulfur dioxide allowances, as of the allowance transfer deadline, in the unit's subaccount not less than the total annual emissions of sulfur dioxide for the previous calendar year from the unit.
- N. **Permit Invalidation:** This permit shall become invalid if construction is not commenced within eighteen months after issuance of such permit, if construction

is discontinued for a period of eighteen months or more; or if construction is not completed within a reasonable time.

- O. **Fugitive Emissions:** The release of fugitive emissions shall comply with the applicable requirements in NDAC 33.1-15-17.
- P. **Annual Emission Inventory/Annual Production Reports:** The owner/operator shall submit an annual emission inventory report and/or an annual production report upon Department request, on forms supplied or approved by the Department.
- Q. **Source Operations:** Operations at the installation shall be in accordance with statements, representations, procedures and supporting data contained in the initial application, and any supplemental information or application(s) submitted thereafter. Any operations not listed in this permit are subject to all applicable North Dakota Air Pollution Control Rules.
- R. **Alterations, Modifications or Changes:** Any alteration, repairing, expansion, or change in the method of operation of the source which results in the emission of an additional type or greater amount of air contaminants or which results in an increase in the ambient concentration of any air contaminant, must be reviewed and approved by the Department prior to the start of such alteration, repairing, expansion or change in the method of operation.
- S. **Air Pollution from Internal Combustion Engines:** The permittee shall comply with all applicable requirements of NDAC 33.1-15-08-01 – Internal Combustion Engine Emissions Restricted.
- T. **Recordkeeping:** The owner/operator shall maintain any compliance monitoring records required by this permit or applicable requirements. The owner/operator shall retain records of all required monitoring data and support information for a period of at least five years from the date of the monitoring sample, measurement, report or application. Support information may include all calibration and maintenance records and all original strip-chart recordings/computer printouts for continuous monitoring instrumentation, and copies of all reports required by the permit.
- U. **Nuisance or Danger:** This permit shall in no way authorize the maintenance of a nuisance or a danger to public health or safety.
- V. **Malfunction Notification:** The owner/operator shall notify the Department of any malfunction which can be expected to last longer than twenty-four hours and can cause the emission of air contaminants in violation of applicable rules and regulations.

- W. **Operation of Air Pollution Control Equipment:** The owner/operator shall maintain and operate all air pollution control equipment in a manner consistent with good air pollution control practice for minimizing emissions.
- X. **Transfer of Permit to Construct:** The holder of a permit to construct may not transfer such permit without prior approval from the Department.
- Y. **Right of Entry:** Any duly authorized officer, employee or agent of the North Dakota Department of Environmental Quality may enter and inspect any property, premise or place at which the source listed in Item I.B of this permit is located at any time for the purpose of ascertaining the state of compliance with the North Dakota Air Pollution Control Rules. The Department may conduct tests and take samples of air contaminants, fuel, processing material, and other materials which affect or may affect emissions of air contaminants from any source. The Department shall have the right to access and copy any records required by the Department's rules and to inspect monitoring equipment located on the premises.
- Z. **Other Regulations:** The owner/operator of the source unit(s) described in Item I.B of this permit shall comply with all State and Federal environmental laws and rules. In addition, the owner/operator shall comply with all local burning, fire, zoning, and other applicable ordinances, codes, rules and regulations.
- AA. **Permit Issuance:** This permit is issued in reliance upon the accuracy and completeness of the information set forth in the application. Notwithstanding the tentative nature of this information, the conditions of this permit herein become, upon the effective date of this permit, enforceable by the Department pursuant to any remedies it now has, or may in the future have, under the North Dakota Air Pollution Control Law, NDCC Chapter 23.1-06.
- BB. **Odor Restrictions:** The owner/operator shall not discharge into the ambient air any objectionable odorous air contaminant which is in excess of the limits established in NDAC 33.1-15-16.

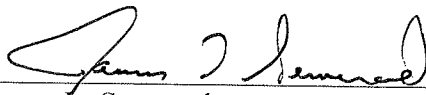

The owner/operator shall not discharge into the ambient air hydrogen sulfide (H₂S) in concentrations that would be objectionable on land owned or leased by the complainant or in areas normally accessed by the general public. For the purpose of complaint resolution, two samples with concentrations greater than 0.05 parts per million (50 parts per billion) sampled at least 15 minutes apart within a two-hour period and measured in accordance with Section 33.1-15-16-04 constitute a violation.

- CC. **Sampling and Testing:** The Department may require the owner/operator to conduct tests to determine the emission rate of air contaminants from the source. The Department may observe the testing and may specify testing methods to be used. A signed copy of the test results shall be furnished to the Department within 60 days of the test date. The basis for this condition is NDAC 33.1-15-01-12

which is hereby incorporated into this permit by reference. To facilitate preparing for and conducting such tests, and to facilitate reporting the test results to the Department, the owner/operator shall follow the procedures and formats in the Department's Emission Testing Guideline.

- IV. **Introduction and Background:**

Montana-Dakota Utilities Co. (MDU) submitted a Permit to Construct (PTC) application on April 30, 2020, for the MDU R.M. Heskett Station. The PTC application proposes the removal of two existing coal-fired boilers (Unit 1 and Unit 2) and ancillary equipment as well as the installation of a new, 88 megawatt (MW) natural gas-fired simple cycle combustion turbine (SCCT), which will be used as a peaking (non-baseload) unit to provide sellable energy. There are no proposed operational or physical changes proposed to the existing simple cycle combustion turbine (Unit 3), or its ancillary equipment.

The MDU R.M. Heskett station will cease current operations as a coal-fired, steam energy generation facility, and will replace all gross energy generation operations with two natural gas-fired SCCTs, which will both act as peaking units. The coal-fired boilers and associated equipment will be removed prior to the commencement of operation of the additional SCCT.

Project proposed changes include the following:

- Removal of the coal-fired boiler rated at 387.63×10^6 Btu/hr (Unit 1 boiler),
- Removal of the coal-fired boiler rated at 916.5×10^6 Btu/hr (Unit 2 boiler),
- Removal of all ancillary equipment associated with the two coal-fired boilers,
- Installation of one 88 MW natural gas-fired SCCT (nominal output is based upon the proposed site elevation, 60% relative humidity, 43 degrees Fahrenheit, and 100% load),

- Installation of one 5,364 bhp natural gas-fired emergency generator, and
- Installation of one 5×10^6 Btu/hr fuel line heater.

The outcome of the project will comprise of an overall air emissions reduction for NO_x, CO, SO₂, PM and greenhouse gases; however, the MDU R. M. Heskett station will remain a major source of criteria pollutants.

In addition, air dispersion modeling of NO_x and air toxics was conducted as a part of the PTC application review process.

Table 1 - Equipment to be Removed

Emission Unit Description ^A	Emission Unit (EU)	Emission Point (EP)	Air Pollution Control Equipment
Coal-fired boiler with a rated heat input of 387.63×10^6 Btu/hr (Unit 1 boiler)	1	1	Electrostatic Precipitator (ESP)
Coal-fired boiler with a rated heat input of 916.5×10^6 Btu/hr (Unit 2 boiler)	2	2	Multiclone, ESP and Limestone addition to bed media
Natural gas-fired IC engine rated at 134 bhp, 100 kW output, built 1963 (Emergency generator engine)	3 ^{B, C}	3	None
Natural gas-fired sand dryer with a rated heat input of 3.0×10^6 Btu/hr (Sand dryer)	5	2	ESP
Unit 1 coal storage silo	M1	M1	Fabric Filter
Unit 1 coal gallery	M2	M1	Fabric Filter
Three Unit 2 coal storage silos	2A, 2B & 2C	M3	Fabric Filters
Ash conveyor system	M4	M4	Fabric Filter
Unit 1 bottom ash silo	M5	M5	Fabric Filter
Sand storage silos	S2B	M6	Fabric Filter
Limestone hopper	S2A	M6	Fabric Filter
Fly ash silo	M7	M7	Fabric Filters
Gasoline storage tank, 1000 gal, built Dec. 2006	M8	M8	Submerged fill pipe
Limestone silo and limestone receiving	M9	M9	Fabric Filter
Limestone conveyor	M11	M11	Fabric Filters

^A Emission units must be removed or permanently decommissioned prior to the commencement of operation of the Unit 4 turbine (EU 12).

Table 2 - Remaining Equipment

Emission Unit Description	Emission Unit (EU)	Emission Point (EP)	Air Pollution Control Equipment
Natural gas-fired combustion turbine nominally rated at 986×10^6 Btu/hr, built 2013 (Unit 3 turbine) (2013) (KKKK)	6	6	Dry Low NO _x (DLN) Combustion
Natural gas-fired in-line heater nominally rated at 2.75×10^6 Btu/hr (Unit 3 in-line heater)	7	7	None
Fugitive emissions	FUG ^A	FUG	None

^A Insignificant unit/activity or no specific emission limit.

Table 3 - New Equipment

Emission Unit Description	Emission Unit (EU)	Emission Point (EP)	Air Pollution Control Equipment
Natural gas-fired combustion turbine nominally rated at 986×10^6 Btu/hr (Unit 4 turbine) (KKKK) (TTTT)	12	12	Dry Low NO _x (DLN) Combustion
Natural gas-fired in-line heater nominally rated at 5×10^6 Btu/hr (Unit 4 in-line heater)	13	13	None
One (4SLB) natural gas-fired emergency generator rated at 5,364 bhp (2020 or newer) (JJJJ) (ZZZZ)	14 ^A	14	None

^A The potential to emit for an emergency stationary reciprocating internal combustion engine (RICE) is based on operating no more hours per year than is allowed by the subparts (40 CFR 60, Subpart JJJJ and 40 CFR 63, Subpart ZZZZ) for other than emergency situations. For engines to be considered emergency stationary RICE under the RICE rules, engine operations must comply with the operating hour limits as specified in the applicable subparts. There is no time limit on the use of emergency stationary RICE in emergency situations.

V. **Potential to Emit (PTE) Emissions:**

Emissions from the facility are as follows:

Table 4 - Unit 4 SCCT Project PTE Calculations (in tons per year)^A

PROJECT POTENTIAL TO EMIT POLLUTANTS (TONS/YEAR)							
Description of PTE Source	PM/PM ₁₀ /PM _{2.5} (tpy)	SO ₂ (tpy)	NO _x (tpy)	CO (tpy)	VOCs (tpy)	HAPs (tpy) ^{A, B}	H ₂ SO ₄ (tpy)
Unit 4 turbine	9.60/9.60/9.60	11.84	312.03	555.03	16.17	1.16	1.53
In-line heater	0.16/0.16/0.16	0.01	2.15	1.80	0.12	0.04	0.00
Emergency generator	0.02/0.02/0.02	0.01	1.18	2.37	0.59	0.11	0.00
Total PTE (without fugitives)	9.78/9.78/9.78	11.86	315.36	559.20	16.88	1.31	1.53
Total PTE (with fugitives)	9.78/9.78/9.78	11.86	315.36	559.20	16.88	1.31	1.53

^A Pollutants are abbreviated as follows:

PM: particulate matter

PM₁₀: particulate matter under 10 microns (<10 µg), includes PM_{2.5}.

PM_{2.5}: particulate matter under 2.5 microns (<2.5 µg)

SO₂: sulfur dioxide

NO_x: nitrogen oxides

VOC: volatile organic compounds

CO: carbon monoxide

^B HAPs: hazardous air pollutants as defined in Section 112(b) of the Clean Air Act Amendments of 1990

See application for more detailed emission calculations.

Table 5 - Emission Reduction After Coal-Fired Boiler Removal (Netting) (in tons per year)

NETTED POTENTIAL TO EMIT POLLUTANTS (TONS/YEAR)							
Time Period	Description of PTE Source	PM/PM ₁₀ /PM _{2.5} (tpy)	SO ₂ (tpy)	NO _x (tpy)	CO (tpy)	VOCs (tpy)	H ₂ SO ₄ (tpy)
Pre-Project ^A	Unit 1	-2.7/-3.1/-2.6	-953.6	-247.8	-203.3	-1.2	-146.0
	Unit 2	-8.5/-216.6/-215.0	-1,166.5	-945.1	-907.6	-5.5	-178.6
Post-Project	Unit 4	9.8/9.8/9.8	11.9	315.4	559.2	16.9	1.5
Netted Emissions ^B		-1.4/-209.9/-207.8	-2,108.2	-877.5	-551.7	10.1	-323.0

^A Emissions based on the 24-month contemporaneous period from 2018 to 2019.

^B Netted emissions are calculated by subtracting the pre-project emissions from the post-project emissions.

Table 6 - Total Post-Project Facility-Wide Emissions (in tons per year) ^A

TOTAL POST-PROJECT POTENTIAL TO EMIT POLLUTANTS (TONS/YEAR)							
Description of PTE Source	PM/PM ₁₀ /PM _{2.5} (tpy)	SO ₂ (tpy)	NO _x (tpy)	CO (tpy)	VOCs (tpy)	HAPs (tpy)	H ₂ SO ₄ (tpy)
Unit 3 ^A	24.4/24.4/24.4	18.4	159.7	263.3	9.7	1.9	NA
Unit 4	9.8/9.8/9.8	11.9	315.4	559.2	16.9	1.3	1.5
Total	34.2/31.2/34.2	30.2	475.1	822.5	26.6	3.2	1.5

^A Emission values from PTC13016 application were used to estimate total emissions.

VI. Applicable Standards:

Table 7 - Applicable Standards

Emission Unit Description	Emission Unit (EU)	Applicable Standards
Unit 4 turbine	12	NDAC 33.1-15-02 NDAC 33.1-15-03 NDAC 33.1-15-05 NDAC 33.1-15-07 NDAC 33.1-15-21 NDAC 33.1-15-12, Subpart KKKK NDAC 33.1-15-12, Subpart TTTT
In-line heater	13	NDAC 33.1-15-02 NDAC 33.1-15-03 NDAC 33.1-15-05
Emergency generator	14	NDAC 33.1-15-03 NDAC 33.1-15-12, Subpart JJJJ 40 CFR 63, Subpart ZZZZ [EPA ^A]

^A The Department has not adopted this subpart; all required documentation should be sent to EPA Region 8.

A. NDAC 33.1-15-02 – Ambient Air Quality Standards

The facility must comply with the Ambient Air Quality Standards (AAQS). Other requirements of this chapter include general prohibitions against harming health, causing damage to plants, animals, other property, and visible degradation. In addition to these standards, compliance with the Department's Air Toxics Policy is required.

Expected Compliance

In the *Criteria Pollutant Modeling Requirements for a Permit to Construct* Department memorandum dated October 6, 2014, dispersion modeling is required if the potential

emissions exceed 100 tpy for NO₂ with some emissions vented from stack heights greater than 1.5 times the nearby building height. The facility's potential NO₂ emissions exceed 100 tons per year and emissions are vented from stack heights greater than 1.5 times nearby building height. Therefore, NO₂ 1-hour and annual air dispersion modeling was conducted to demonstrate compliance with NAAQS. Modeling was also conducted for Class II increment consumption.

Table 8 below, as well as the accompanying Air Quality Impact Analysis demonstrate that the modeled 1-hour NO₂ design values of 149.86 µg/m³, 150.51 µg/m³ and 149.69 µg/m³, are less than the NAAQS of 188 µg/m³. The modeled annual NO₂ design values of 9.92 µg/m³, 10.31 µg/m³ and 10.18 µg/m³, are less than the NAAQS of 100 µg/m³. Therefore, compliance with this chapter is expected.

Table 8 - Cumulative – Ambient Air Quality Standards (AAQS) Results Summary

POLLUTANT	AVERAGING TIME	MODELED IMPACT (µg/m ³)	Class II/ AAQS SIL (µg/m ³)	BACKGROUND (µg/m ³)	TOTAL IMPACT (µg/m ³)	NAAQS/ NDAASQ (µg/m ³)	PASSED (Y/N)

Air Toxics Policy (Policy for the Control of Hazardous Air Pollutant Emissions in North Dakota) Expected Compliance

The Air Toxics Policy (Policy) establishes guidelines to evaluate HAPs emitted into the ambient air (off-property). The evaluation includes a determination of both carcinogenic and non-carcinogenic risks due to the HAPs emissions. Individual HAP species, emission rates (gram/second), building downwash effects, and distances to nearby sources are modeled. The modeled HAP concentrations (µg/m³) are used to calculate both a maximum individual carcinogenic risk (MICR) and a hazard index (HI). Modeled HAPs include those with potential to emit greater than 0.1 tpy. Tier 3 modeling (AERMOD v. 19191) is utilized to predict the following impacts:

Table 9 - Maximum Individual Carcinogenic Risk and Hazard Index Analyses

HAP	MICR	HAZARD INDEX (HI) (MICR/CR Ratio)
Acetaldehyde	3.8×10^{-10}	3.3×10^{-5}
Acrolein	--	1.0×10^{-3}
Benzene	4.0×10^{-10}	9.6×10^{-5}
1,3-Butadiene	5.5×10^{-11}	1.2×10^{-6}
Ethyl benzene	3.4×10^{-10}	2.2×10^{-6}
Formaldehyde	1.1×10^{-8}	0.02
Naphthalene	1.9×10^{-10}	6.2×10^{-7}
PAH	--	--
Propylene Oxide	4.6×10^{-10}	7.8×10^{-5}
Toluene	--	2.2×10^{-5}
Xylene	--	3.7×10^{-6}
Total	1.31×10^{-8}	0.022
Standard	1×10^{-5}	1.0
Pass (Y/N)	Yes	Yes

The calculated MICR is the probability of an individual developing cancer after being exposed to the highest concentration of HAPs over a defined period of time. Only HAPs with known or possible carcinogenic risks are used to calculate the MICR. The MICR threshold stated in the Policy is 1×10^{-5} , which represents a probability of one person out of 100,000 people. The MICR calculated above at 1.31×10^{-8} is less than 1×10^{-5} and compliance with Air Toxics Policy is expected.

The HI calculation incorporates both carcinogenic and non-carcinogenic HAPs with acute and/or chronic health effects to determine both compliance with 1-hour and 8-hour guidelines concentrations. The HI is a sum of all modeled concentrations and guideline concentration ratios. A HI of less than 1 indicates that HAP modeled concentration are less than 1-hour and 8-hour guideline concentrations. The HI calculated above of 0.022 is less than 1.0 and compliance with the Air Toxics Policy is expected.

Total combined HAP emissions are low, with the MDU R.M. Heskett Station emissions at 3.2 tpy. Formaldehyde is the largest single HAP at 0.53 tpy, and compliance with applicable NSPS/MACT standards is expected. The facility is expected to comply with the ambient air quality standards and the *Air Toxics Policy*¹.

B. NDAC 33.1-15-03 – Restriction of Emission of Visible Air Contaminants

This chapter restricts the amount of visible air contaminants, primarily particulate matter, from incinerators and fuel-burning units.

¹ August 25, 2010 NDDOH *Policy for the Control of Hazardous Air Pollutant (HAP) Emissions in ND (aka Air Toxics Policy)*, https://deq.nd.gov/publications/AQ/policy/Modeling/Air_Toxics_Policy.pdf

Expected Compliance

Based on the fuels used, visible air emissions are expected to be well below the 20% opacity limit established by this chapter.

Table 10 - Opacity Limits

Emission Unit Description	EU	Pollutant/ Parameter	Emission Limit
Unit 4 turbine	12	Opacity	20% ^A
In-line heater	13	Opacity	20% ^A
Emergency generator	14	Opacity	20% ^A

^A 40% permissible for not more than one six-minute period per hour.

C. **NDAC 33.1-15-05-Emissions of Particulate Matter Restricted**

This chapter applies to any operation, process, or activity from which particulate matter is emitted except for the indirect heating in which the products of combustion do not come into direct contact with process materials.

Expected Compliance

Table 11 - Particulate Matter Limits

Emission Unit Description	EU	Pollutant/ Parameter	Emission Limit
Unit 4 turbine	12	PM	0.324 lb/MMBtu
In-line heater	13	PM	0.710 lb/MMBtu

Particulate matter emission limits are well below applicable standards when units are fueled by pipeline quality natural gas, therefore compliance with this chapter is expected.

D. **NDAC 33.1-15-06-Emissions of Sulfur Compounds Restricted**

This chapter applies to any installation in which fuel is burned in which the SO₂ emissions are substantially due to the sulfur content of the fuel burned and in which the fuel is burned primarily to produce heat. This chapter is not applicable to installations which are subject to a SO₂ emission limit under Chapter 33.1-15-12, Standards for Performance for New Stationary Sources, or installations which burn pipeline quality natural gas.

Expected Compliance

The facility is restricted to combusting only natural gas containing no more than 2 grains of sulfur per 100 standard cubic feet, therefore compliance with this chapter is expected.

D. **NDAC 33.1-15-07 – Control of Organic Compounds Emissions**

This chapter requires compressors handling volatile organic compounds must be equipped and operated with properly maintained seals.

Expected Compliance

Based on Department experience with similar sources, the facility is expected to comply with this chapter.

E. **NDAC 33.1-15-12 - Standards of Performance for New Stationary Sources [40 Code of Federal Regulations Part 60 (40 CFR Part 60)]**

This chapter adopts most of the Standards of Performance for New Stationary Sources (NSPS) under 40 CFR Part 60. The facility is subject to subparts listed under 40 CFR Part 60 which have been adopted by the North Dakota Department of Environmental Quality.

Table 12 - NSPS Requirements

Emission Unit Description	Emission Unit (EU)	Applicable Standards
Unit 4 turbine	12	NDAC 33.1-15-12, Subpart KKKK NDAC 33.1-15-12, Subpart TTTT
Emergency generator	14	NDAC 33.1-15-12, Subpart JJJJ

1. **Subpart A-General Provisions**

Subpart A contains the NSPS General Provisions, since the facility is subject to one or more NSPS (NDAC 33.1-15-12/40 CFR 60) it is subject to this subpart.

Expected Compliance

Compliance with the requirements of Subpart A is expected through compliance with each applicable NSPS subpart.

2. **Subpart KKKK – Standards of Performance for Stationary Combustion Turbines, as incorporated by reference into NDAC 33.1-15-12**

This subpart establishes emission standards and compliance schedules for the control of NO_x and SO₂ emissions from stationary combustion turbines that commenced construction, modification, or reconstruction after February 18, 2005.

Expected Compliance

The SCCT (EU 12) is subject to this subpart. As such it will have a dry low NO_x combustion control installed as well as a NO_x continuous emissions monitor (CEMs) per 40 CFR 60.4340(b) and 60.4345, which will assess excess emissions based on a 4-hour rolling average.

Table 13 - NO_x Emissions Per Operational Status

Operational Status	NO _x Hourly Emissions (lb/hr)	Total Number of Hours
Normal Operations	81.1	2,859
Start-up/Shutdown	4.6	450
Turn-down	515.0	691

Table 14 - SO₂ Emissions Per Operational Status

Operational Status	NO _x Hourly Emissions (lb/hr)	Total Number of Hours
Normal Operations	6.6	2,859
Start-up/Shutdown	0.41	450
Turn-down	6.6	691

Table 15 - Emission Limits

Emission Unit Description	EU	EP	Pollutant / Parameter	Emission Limit
Natural gas-fired combustion turbine nominally rated at 986 x 10 ⁶ Btu/hr (Unit 4 turbine)	12	12	NO _x : >50 MW (gross) & >0°F	15 ppmvd @ 15% O ₂ or 54 ng/J (0.43 lb/MWh) ^{A, B, C, D}
			NO _x : ≤50 MW (gross) or <0°F	96 ppmvd @ 15% O ₂ or 590 ng/J (4.7 lb/MWh) ^{A, B, C, D}
			NO _x	515.8 lb/hr ^H
			SO ₂	110 ng/J (0.90 lb/MWh) (gross) or 0.060 lb/MMBtu (fuel use) ^E
			CO ₂	50 kg CO ₂ /GJ heat input (120 lb CO ₂ /MMBtu) ^{F, G}

^A CEMs installed in lieu of annual performance tests (40 CFR 60.4340(b)).

^B CEMs installation, operation, and performance testing must meet the applicable standards of 40 CFR 60 Subpart KKKK.

^C Based on a 4-hr rolling average.

^D The higher NO_x limit emission limit applies for the entire hour if at any point in the hour the unit was subject to a higher limit.

- E Sulfur content of the fuel must be determined using total sulfur methods per 40 CFR 60.4415 and 60.4370.
- F Emissions standards must be met at all times; however, compliance must be determined only at the end of each applicable operating month.
- G Emission limit is based on operations that supply less than or equal to its design efficiency (33.34%) or 50%, whichever is less, times its potential electric output as net-electric sales on either a 12-operating month or a 3-year rolling average basis and combusts > 90% natural gas.
- H Based on a 1-hr average.

NO_x concentration is dependent upon the combustion temperature; therefore, NO_x emission limits vary based on ambient temperatures.

For demonstrating compliance with SO₂ emission limits, the facility may conduct SO₂ performance tests per §60.4415(a) or monitor sulfur content of the fuel combusted in the turbine per §60.4360. A representative fuel sample would be collected following ASTM D5287 (incorporated by reference, see §60.17) for natural gas or ASTM D4177 (incorporated by reference, see §60.17) for oil, per 60.4415.

Compliance with this chapter is expected.

3. **Subpart TTTT – Standards of Performance for Greenhouse Gas Emissions for Electric Generating Units, as incorporated by reference into NDAC 33.1-15-12**

This subpart establishes emission standards and compliance schedules for the control of greenhouse gas (GHG) emissions from a stationary combustion turbine that commences construction after January 8, 2014. An applicable unit shall be referred to as an affected electrical generating unit (EGU).

An affected EGU (per the definition in 40 CFR 60.5580), with a base load rating greater than 260 GJ/h (250 x 10⁶ Btu/hr) of fossil fuel and capable of selling more than 25 MW to a power distribution system is subject to this subpart. Therefore, the Unit 4 turbine is considered an affected EGU per 40 CFR 60, Subpart TTTT and must comply with all applicable standards set forth in this rule.

Expected Compliance

Table 16 - Emission Limits

Emission Unit Description	EU	Pollutant/ Parameter	Emission Limit	Compliance Method
Unit 4 turbine	12	CO ₂	50 kg CO ₂ /GJ heat input (120 lb CO ₂ /MMBtu) ^{A, B}	Notification and Recordkeeping

^A Emissions standards must be met at all times; however, compliance must be determined only at the end of each applicable operating month.

- B Emission limit is based on operations that supply less than or equal to its design efficiency (33.34%) or 50%, whichever is less, times its potential electric output as net-electric sales on either a 12-operating month or a 3-year rolling average basis and combusts > 90% natural gas.

Within 30 days after the end of a compliance period, an initial compliance determination must be made with respect to the applicable emissions limits. Since MDU R.M. Heskett is subject to the Acid Rain Program, emissions reporting is required to begin under 40 CFR 60.5525(c).

Compliance with this chapter is expected.

4. **Subpart JJJJ - Standards of Performance for Stationary Spark Ignition Internal Combustion Engines, as incorporated by reference into NDAC 33.1-15-12**

This rule states that natural gas-fired emergency generators (spark-ignited) greater than 500 bhp manufactured after July 1, 2010 are subject to this subpart. The emergency generator (EU 14) is an affected unit according to this rule.

Expected Compliance

Table 17 - NSPS JJJJ Requirements

Emission Unit Description	EU	Requirements
Emergency generator	14	<ul style="list-style-type: none">-The emergency engine may be operated for up to 50 hours or less per year (January through December) for non-emergency uses.-The emergency engine may be operated for a maximum total of 100 hours per year (January through December) for non-emergency uses such as maintenance and testing (50 hours of general non-emergency use must be counted toward the 100 total hours of use).

Table 18 - NSPS JJJJ Emission Limits

Emission Unit Description	EU	Pollutant / Parameter	Emission Limit
Emergency generator	14	NO _x	2.0 g/hp-hr or 160 ppmvd ^A
		CO	4.0 g/hp-hr or 540 ppmvd ^A
		VOC	1.0 g/hp-hr or 86 ppmvd ^A

^A The emission limits in g/hp-hr and ppmvd (at 15% O₂) are from 40 CFR 60, Subpart JJJJ.

The emergency generator (EU 14) is subject to the requirements of this subpart. Compliance with this subpart is expected.

F. **Chapter 33.1-15-14 – Designated Air Contaminant Sources, Permit to Construct, Minor Source Permit to Operate, Title V Permit to Operate**

This chapter requires the facility to obtain a Permit to Construct prior to installation of sources of air pollution. This chapter also applies to Permit to Operate requirements for facilities that have sources of air pollution.

Expected Compliance

The company has submitted an application for a Permit to Construct and has met those requirements.

G. **Chapter 33.1-15-15 – Prevention of Significant Deterioration of Air Quality**

A Prevention of Significant Deterioration (PSD) review could potentially apply to this facility if it is classified as a “major stationary source” under Chapter 33.1-15-15.

This facility source category will have a PSD major source threshold of 250 tpy, not including fugitive emissions. Due to annual NO_x emissions greater than 250 tpy the facility is classified as a “major stationary source”; therefore, additional construction and modification projects may be subject to PSD review if the emissions increase due to the project exceeds the Significant Emission Rates (SERs) in Table 19 below.

Expected Compliance

Table 19 - Prevention of Significant Deterioration (PSD) Requirements

Pollutant	Project Emissions	Past Actual Emissions ^A	Net Emissions Increase	PSD Significant Emission Rate
NO _x	315.36	1,192.3	-877.49	40
PM ₁₀	9.78	219.7	-209.9	15

Pollutant	Project Emissions	Past Actual Emissions ^A	Net Emissions Increase	PSD Significant Emission Rate
PM _{2.5}	9.78	217.6	-207.81	10
SO ₂	11.86	2,120.1	-2,108.19	40
VOC	16.88	6.7	10.18	40
H ₂ SO ₄	1.53	324.6	-323.04	7
CO ₂ e	267,276	669,155	-401,879	75,000

A Past actual emissions based on 24-month contemporaneous period from 2018 to 2019, which is within five years of construction.

Based on the table above, emissions from the new equipment proposed in ACP-17983 v1.0 are expected to be well below the PSD SERs; therefore, the new units are not subject to PSD review.

H. **Chapter 33.1-15-16 – Restriction of Odorous Air Contaminants**

The owner/operator shall not discharge into the ambient air any objectionable odorous air contaminant which is in excess of the limits established in NDAC 33.1-15-16.

Expected Compliance Status

Based on Department experience with similar sources, the facility is expected to comply with this chapter.

H. **Chapter 33.1-15-21 – Acid Rain Program**

The SCCT will be considered a utility under the requirements of Chapter 33.1-15-21. Therefore, the owner/operator must apply for, and obtain, an Acid Rain Permit in accordance with NDAC 33-15-21-08.1. In addition, the owner/operator must hold sulfur dioxide allowances, as of the allowance transfer deadline, in the unit's subaccount not less than the total annual emissions of sulfur dioxide for the previous calendar year from the unit. Monitoring of emissions must be accomplished in accordance with NDAC 33-15-21-09 (40 CFR 75).

Expected Compliance Status

The proposed Unit 4 turbine at MDU R.M. Heskett station must operate the unit in compliance with a complete Acid Rain permit application including any application for permit renewal or a superseding Acid Rain permit issued by the North Dakota Department of Environmental Quality, Division of Air Quality

MDU R.M. Heskett has submitted an Acid Rain Permit Application and compliance with this chapter is expected.

I. **Chapter 33.1-15-22 – Emission Standards for Hazardous Air Pollutants for Source Categories**

This chapter adopts most of the National Emission Standards for Hazardous Air Pollutants for Source Categories (MACT) under 40 CFR Part 63.

1. **Subpart A-General Provisions**

This chapter adopts the 40 CFR Part 63 regulations, also known as the Maximum Achievable Control Technology (MACT) standards, which regulates HAPs from regulated source categories. Typically, these standards apply to major sources of air pollution that are a regulated source category. In addition to the major source requirements, some of the regulations have “area source” standards (for non-major sources). Some of the area source standards have not been adopted by the Department and compliance will be determined by the United States Environmental Protection Agency (USEPA) (e.g. 40 CFR Part 63, Subpart ZZZZ area source provisions have not been adopted by the Department).

Expected Compliance

Subpart A contains the MACT General Provisions. Compliance with the requirements of Subpart A is expected through compliance with each applicable MACT subpart.

2. **Subpart ZZZZ-National Emissions Standards for Hazardous Air Pollutants for Stationary Reciprocating Internal Combustion Engines**

The facility appears to have engines subject to the requirements under this subpart. The requirements of Subpart ZZZZ for the engines are met by complying with the requirements of NDAC 33.1-15-12, Subpart JJJJ for EU 14.

Expected Compliance

Table 20 - ZZZZ Requirements

Emission Unit Description	Emission Unit (EU)	Applicable Standards
One (4SLB) natural gas-fired emergency generator rated at 5,364 bhp	14	Comply with NDAC 33.1-15-12, Subpart JJJJ ^{A, B}

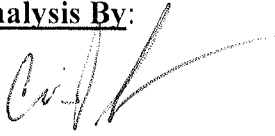

^A The Department has not adopted the area source requirements of this subpart; EPA Region 8 is the implementing and enforcement authority for this subpart at minor sources of hazardous air pollutants.

^B The requirements of Subpart ZZZZ for the engine is met by complying with the requirements of NDAC 33.1-15-12 [40 CFR 60], Subpart JJJJ.

Conclusions and Recommendations:

The facility is expected to comply with applicable federal and state rules. No comments were received during the 30-day public comment period. It is recommended that Permit to Construct No. ACP-17983 v1.0 be issued for the MDU R.M. Heskett Station.

A.7 – Little Knife Gas Plant

1 Introduction and Representative Operations

Petro-Hunt, L.L.C. (Petro-Hunt) – Little Knife Gas Plant (LKGP) is comprised of numerous fuel gas combustion units, process equipment, tankage, flares, and a sulfur recovery process controlled by an incinerator. The major emissions source onsite is the 2-stage 2-bed Cold Bed Absorption (CBA) sulfur recovery unit (SRU) tail gas incinerator. The LKGP is located approximately 18 miles southwest of Killdeer, North Dakota in Billings County.

LKGP receives associated gas produced from North Dakota oilfields. Since the development of the Bakken shale formation, LKGP has continued to experience a decrease in sour gas received onsite. This is primarily due to the low concentrations of H₂S in Bakken shale gas paired with an increase in Bakken shale gas delivered to the facility. To determine representative operations for the facility, data from 2016–2018 was used. 2016–2018 was chosen since the SRU was converted from a four-stage unit to a two-stage Claus unit with cold bed absorption (CBA) in 2015. The SRU tail gas incinerator combusts the remaining unreacted H₂S after the gas passes through the SRU process. The SRU tail gas incinerator accounted for at least 85% of the total facility emissions since 2016, Table 1 displays the annual emissions reported in tons from 2016-2018.

Table 1: Facility Emissions in Tons

Year	PM _{2.5}	PM ₁₀	SO ₂	NO _x	CO	VOC	Total
2016	2	2	248	22	18	2	293
2017	1	1	389	19	16	2	428
2018	1	1	363	22	18	1	406

The SO₂ emissions displayed in Table 1 are primarily from the operation of the tail gas incinerator on the SRU. Due to the significant amount of emissions from the SRU compared to the rest of the facility, the Department focused the review of additional controls on the SRU process.

2 SO₂ Emissions Controls and Representative History

2.1 SO₂

2.1.1 SO₂ Emissions Controls

The historical controls at Petro-Hunt LKGP consisted of two sulfur recovery units, a three-stage four-bed CBA unit and a standard 3-stage Claus unit. The units recovered approximately 98% of the sulfur from the acid gas and converted it to elemental sulfur. The remainder of the acid gas is converted from H₂S to SO₂ by the tail gas incinerator. SO₂ emissions from the incinerator are monitored by a continuous emission rate monitoring system (CERMS).

In September 2015 due to operational difficulty arising from the decrease in inlet H₂S gas to the facility, the sulfur recovery process was modified to handle the reduced H₂S. The three-stage Claus unit was removed from service and the four-bed CBA was converted to a two-stage Claus unit with CBA.

2.1.2 SO₂ Emissions History

Over the years 2016–2018, the SRU recovered approximately 94% of the sulfur entering the unit. The total sulfur recovered, the SO₂ emissions from the tail gas incinerator and the calculated sulfur mass emitted (SO₂ is twice as heavy as elemental sulfur) was used to calculate the SRU recovery efficiency. This information is displayed in Table 2.

Table 2: Sulfur Recovery Unit Efficiency

Year	Sulfur Recovered (tons)	SO ₂ Emissions from Incinerator (tons)	Sulfur Emissions (tons)	Sulfur Recovery (%)
2016	2975	242	121	96%
2017	2504	315	157	94%
2018	2284	363	181	93%
Average	2588	307	153	94%

The other potential significant source of SO₂ emissions from the facility occurs when a process malfunction occurs, and the facility needs to route H₂S inlet or process gas to the facility flare. This does not happen on a routine basis and there is no ability to reduce the emissions during these malfunction events. From 2016–2018 a combined total of 80 tons of SO₂ were emitted from the facility flare, with 74 tons SO₂ occurring in 2017.

3 SO₂ Analysis

3.1 SO₂ Technologies Evaluated

The reasonable progress controls evaluated by LKGP and determined to be technically feasible are listed in Table 3. Expected annual emissions were based on the three-year average SO₂ emissions from the SRU incinerator at LKGP (Table 2). LKGP expects no operational changes, therefore, these emissions are also repetitive of future expected emissions.

Table 3: Reasonable Progress SO₂ Controls

Control Technology	Control Technology Abbreviation	Emissions (tons/year)
Existing SRU (baseline)	--	307
Acid Gas Injection	AGI	0

LKGP also evaluated a catalyst replacement in the SRU reactors to increase the efficiency of unit. Catalyst replacement due to degradation and/or fouling happens on a regular basis and is not considered for reasonable progress controls.

3.1.1 Acid Gas Injection

Acid gas injection (AGI) is a process in which acid gases (H₂S and CO₂) are injected into deep underground wells to dispose of the acid gases produced during the sweetening process of natural gas

at a gas processing facility. Installation of AGI eliminates the need for a facility to operate a SRU since the acid gases produced from the natural sweetening process are disposed of underground versus being processed in a SRU.

AGI eliminates all SO₂ emissions except for those emissions due to a malfunction of the injection equipment. When a malfunction occurs, the gas goes to a flare which will combust the H₂S to form SO₂.

3.2 Step 1 – Cost of Compliance

The cost of compliance for the reasonable progress controls are listed in Table 4.

Table 4: SO₂ Cost of Compliance

Control Technology	Emissions (tons/year)	Annual Emission Reduction (tpy)	Annualized Total Cost (\$)	Cost of Compliance (\$/ton)
Existing SRU (baseline)	307			
Acid Gas Injection	0	307	490,009	1,598
Acid Gas Injection ^A	0	307	628,523	2,050

^A AGI includes redundant compressor and plumbing costs

A detailed breakdown of the costs listed in Table 4 can be found in LKGP's submitted four factors analysis.¹ The Department has reviewed these costs and believes them to be accurate.

If AGI is installed, all the routine SO₂ emissions from the current SRU process will be eliminated. This equates to a reduction of 307 tons SO₂ per year from the baseline emissions. Fiscally, AGI installation requires an estimated annualized cost of \$490,000 and SO₂ removal cost of \$1,600 per ton.

As mentioned in Table 4, if redundant AGI equipment is installed, the estimated annualized cost increases to \$628,500 and SO₂ removal cost increases to roughly \$2,100 per ton. Redundant AGI equipment would be utilized to dispose the acid gas in the event when a malfunction occurs. These malfunctions are generally unplanned, short duration-episodes (a few hours) with very high SO₂ emission rates that vary from year-to-year. Without redundancy, controlling emissions during malfunctions is not feasible and the acid gas is flared to prevent the release of high concentrations of H₂S.

3.3 Step 2 – Time Necessary for Compliance

Petro-Hunt indicated installation of AGI would require at least 72 months to complete.² The time necessary for compliance is not a limiting factor when determining additional reasonable controls for the LKGP since it could be installed prior to the end of the second planning period.

¹ Appendix B.7.b. PDF page 1300-1311.

² Appendix B.7.b. PDF page 1298.

3.4 Step 3 – Energy and Non-Air Quality Environmental Impacts

3.4.1 Energy and Non-Air Quality Environmental Impacts

LKGP's submitted four factors analysis indicated various energy and non-air quality environmental impacts ranging from increased electrical demand to added fuel cost.³ While these impacts can be significant, none of the impacts eliminate AGI as a potential add-on control option.

3.5 Step 4 – Remaining Useful Life

Based on the information provided to the Department, the Petro-Hunt LKGP is expected to operate beyond the life of the control equipment.⁴ Therefore, remaining useful life was not considered.

³ Appendix B.7.b. PDF page 1299.

⁴ Appendix B.7.b. PDF page 1299.

A.8 – Hess Tioga Gas Plant

**BEFORE
THE DEPARTMENT OF ENVIRONMENTAL QUALITY
STATE OF NORTH DAKOTA**

IN THE MATTER OF:

Hess Tioga Gas Plant, LLC

**ADMINISTRATIVE CONSENT
AGREEMENT**

Case No. 21-169 APC

The North Dakota Department of Environmental Quality (Department), together with **Hess Tioga Gas Plant, LLC (Respondent)**, agree to settle this administrative action on the following terms:

PRELIMINARY STATEMENT

1. The Department is the state agency responsible for administering and enforcing the state's air pollution control laws and rules, N.D.C.C. ch. 23.1-06 and N.D. Admin Code art. 33.1-15, and has the authority to enter into this Administrative Consent Agreement under N.D.C.C. chs. 23.1-06 and 28-32.
2. Respondent is a Delaware limited liability company in the business of owning and operating a gas processing plant in North Dakota.
3. The parties enter into this Agreement to avoid the expense of litigation and ensure prompt compliance with the state's environmental laws. The Agreement is in the public interest and has been chosen as the most appropriate means of resolving this matter.

STIPULATIONS & VIOLATIONS

4. Respondent owns and operates a gas processing plant located in Tioga, North Dakota (Tioga Gas Plant).
5. Respondent is subject to the requirements of N.D.C.C. ch. 23.1-06 and the rules adopted thereunder.
6. On January 16, 2019, the Department issued Respondent Permit to Operate No. AOP-28424 v5.1 (Permit to Operate) for the Tioga Gas Plant, which is **Attachment A** to this Agreement and incorporated herein by reference. Included in Respondent's Permit to Operate are Clark engines, source units C-1A through 1G (collectively "the Clark engines"). Clark engines C-1D and C-1F have been retrofitted in order to reduce emissions. The non-retrofitted Clark engines are C-1A, C-1B, C-1C, C-1E, and C-1G.
7. While reviewing the WBI Energy Transmission (WBI) Permit to Construct application dated February 14, 2020, the Department determined that WBI

triggered a cumulative air dispersion modeling analysis for the 1-hour NO₂ National Ambient Air Quality Standards (NAAQS) and that the Tioga Gas Plant should be included in the WBI's cumulative modeling analysis.

8. In a letter dated March 4, 2020, the Department notified Respondent that preliminary air dispersion modeling using permitted NO_x emission limits, conducted by the Department in association with the review of the WBI application, identified modeled 1-hour NO₂ concentrations (referred to as "design value") above the 1-hour standard. The Department asserted that the modeled NO₂ concentrations were primarily due to permitted emissions from the Clark engines and not necessarily actual emissions from the Tioga Gas Plant.
9. Based on Potential to Emit calculations and conservative operations assumptions used in the modeling, the Department alleges that Respondent's operation of the Tioga Gas Plant has violated N.D. Admin. Code § 33.1-15-02-07(1), which states that "no person may cause or permit the emission of contaminants to the ambient air from any source in such a manner and amount that causes or contributes to a violation in the ambient air of those standards stated in section 33.1-15-02-04."
10. This Agreement is for the purpose of settlement only. Respondent admits to the Department's jurisdiction but does not admit to the violations alleged in Paragraph 9. Respondent agrees that the Department may consider this matter and any enforcement documents relating to this matter – including inspection reports, the March 4, 2020, letter, and this Agreement – when determining Respondent's compliance history in connection with any future enforcement or permitting action by the Department against Respondent. In any such action, Respondent shall be stopped from objecting to the above-referenced documents being considered by the Department or entered into evidence in any administrative or judicial proceeding for the purpose of determining Respondent's compliance history.

SETTLEMENT TERMS

NOW, THEREFORE, in consideration of the foregoing and the mutual covenants and conditions in this Agreement, and desiring to be legally bound, the Parties agree as follows:

11. Respondent agrees to pay an administrative penalty of Sixty-Five Thousand Dollars (\$65,000), of which Forty-Five Thousand Dollars (\$45,000) shall be suspended and may be ultimately dismissed according to the provisions of Paragraph 14 of these Settlement Terms. The remaining Twenty Thousand (\$20,000) shall be due within 30 days after this Agreement's effective date. Payment of the penalty shall be in a check made payable to the North Dakota

Department of Environmental Quality, shall reference Case No. 21-169 APC, and shall be directed to the attention of L. David Glatt, Director, North Dakota Department of Environmental Quality, 4201 Normandy St., Bismarck, ND 58503-1324. If any payment required by this Agreement is not made, or if any negotiable instrument presented as payment is not honored, the Department may file a civil action to collect the amount due under this Agreement plus interest, attorney's fees, and costs. In any collection action, the validity, amount, and appropriateness of penalties is not subject to review.

12. Compliance Measures. Respondent shall comply with the following Compliance Measures:

a. The non-retrofitted Clark engines will be removed from service before July 1, 2024. The retrofitted Clark engines shall be removed from service before June 30, 2025.

b. Until the Clark engines are removed from service, Respondent shall:

i. Evaluate and implement operational controls, as appropriate, designed to reduce operating time for the Clark engines, within 90 days of this Agreement's effective date. When operationally practical, the Clark engines, specifically the non-retrofitted Clark engines, will be the last compressors to be activated and the first to be taken offline at the Tioga Gas Plant.

1. Respondent shall submit a semiannual report to the Department detailing the operational controls, designed to reduce the operating time of the Clark engines, implemented at the Tioga Gas Plant. The semiannual report must also show the dates of operation and number of hours each Clark engine was operated during the period.

ii. Install one NO₂ ambient monitoring station. Respondent shall continue to operate the NO₂ ambient monitoring station until the Clark engines are removed from service.

1. Respondent shall submit a proposal to the Department to determine the location of the NO₂ ambient monitor station within 60 days of this Agreement's effective date. Respondent shall install the NO₂ ambient monitor station within 90 days after the Department's written approval.

2. Respondent shall submit quarterly ambient air quality monitoring data and quality assurance reports to the Department. Information to be included in the quarterly reports can be found in the Permit to Operate, Condition 10.G.

3. If any exceedance of the ambient air quality standards are measured by the NO₂ ambient monitor, Respondent shall investigate the cause of the exceedance and promptly provide a report of the results of its investigation to the Department.
 - iii. Complete a study of compression needs and submit a Permit to Construct application for the Tioga Gas Plant to the Department, within 18 months of this Agreement's effective date, to undertake permitting actions, as necessary, to remove the Clark engines from service at the Tioga Gas Plant as described in this Paragraph.
 - c. Between July 1, 2024, and the date the retrofitted Clark engines are removed from service, Respondent shall only operate the retrofitted Clark engines in a back-up capacity as needed during non-normal operations at the Tioga Gas Plant.
13. **Reservation of Rights.** The Department reserves the right to enforce this Agreement and bring new enforcement action should Respondent fail to complete the Compliance Measures required by this Agreement. The Department also reserves the right to bring new enforcement action for any additional violations disclosed under this Agreement.
14. **Suspended Penalty.** The Department shall dismiss the Forty-Five Thousand Dollar (\$45,000) suspended penalty if Respondent complies with the conditions of Paragraph 12 of these Settlement Terms. Failure to complete the conditions of Paragraph 12 according to the schedule provided in these Settlement Terms shall result in the entire Forty-Five Thousand Dollar (\$45,000) suspended penalty becoming immediately due and payable. Upon notification from the Department, Respondent shall immediately pay the suspended penalty according to the terms of Paragraph 11. Payment of the suspended penalty does not relieve Respondent of its obligation to complete the remaining conditions of these Settlement Terms, and Respondent shall complete all the Compliance Measures as provided in these Settlement Terms.

GENERAL TERMS

15. Respondent agrees that it was properly notified of the violations listed herein.
16. Respondent acknowledges that, regarding the violations listed herein, it is knowingly and voluntarily waiving the rights and procedures that would otherwise protect it and that it would have in any formal administrative adjudicatory proceeding or any civil action in a court of law, including the right to the filing of a notice of intent to file suit, to present evidence and witnesses on its behalf, to cross-examine Department's witnesses, to a jury trial, and to administrative and judicial review.

17. Respondent agrees that an administrative order may be entered incorporating the Agreement's terms and agrees that such an order may be enforced by a court of competent jurisdiction. Respondent agrees that it will not contest Department's jurisdiction to compel compliance with such an order in any subsequent enforcement proceedings. Nothing herein shall be construed as limiting Department's right to seek penalties for violations of such an order.
18. Any judicial action brought by either party to enforce or adjudicate any of the Agreement's terms, or an order incorporating the Agreement's terms, shall be brought in the Burleigh County Court in the State of North Dakota (South Central Judicial District).
19. If any term of this Agreement is declared by a court having jurisdiction to be illegal or unenforceable, the validity of the remaining terms will not be affected and, if possible, the rights and obligations of the parties are to be construed and enforced as if the Agreement did not contain that term.
20. The Agreement shall constitute full settlement of the violations listed herein but does not limit Department from taking enforcement action concerning other violations.
21. No failure by Department to enforce any of the Agreement's terms after any breach or default will be deemed as a waiver of its rights regarding that breach or default, nor will such failures be construed as a waiver of the right to enforce all of the Agreement's terms on any further breach or default.
22. This Agreement constitutes the entire agreement between the parties. Except as otherwise provided in the Agreement, no amendment, alteration, or addition to the Agreement shall be binding unless reduced to writing and signed by both parties.
23. The Agreement shall apply to, and be binding on, the parties, their officers, agents, servants, employees, successors, and assigns.
24. No change in ownership of any property, or in Respondent's corporate status, shall in any way alter Respondent's obligations and responsibilities under this Agreement.
25. Each party shall bear its own costs incurred in this action, including attorney fees.
26. The Agreement becomes effective when signed by both parties.
27. Respondent enters into the Agreement freely and voluntarily. Respondent discussed this Agreement with its attorney.

1 Introduction and Representative Operations

Hess Tioga Gas Plant, LLC (Hess) – Hess Tioga Gas Plant (TGP) is comprised of numerous boilers, heaters, compressor engines, turbines, storage tanks, process equipment, flares, and a sulfur recovery process controlled by an incinerator. Most of the emissions are sourced from the compressor engines and the amine gas sweetening unit (the SRU tail gas incinerator). Tioga is located just to the east of Tioga, North Dakota in Williams County.

The average annual amount of inlet gas received, natural gas produced, and sulfur recovered from 2015 through 2018 is listed in Table 1. The time period of 2015–2018 was chosen as representative since Hess TGP completed a plant expansion in 2014, allowing the facility to process more inlet gas.

The process data does not directly correlate with the emissions from the facility but helps to show consistent operations over the recent years from the facility. With this consistent operation, emissions from this time period can be averaged to determine representative baseline emissions in order to evaluate additional feasible controls. See Table 1 for detailed information.

Table 1: Process Data from 2015-2018

Year	Gas Received (MMscf)	Gas Produced (MMscf)	Sulfur Produced (tons)
2015	70,800	36,200	8,970
2016	62,200	36,300	8,030
2017	63,900	39,200	8,170
2018	70,200	45,100	8,240

Hess TGP's future operations are expected to be in line with the 4-year average of 2014–2018.

2 NO_x and SO₂ Emissions Controls and Representative History

The emissions sources which contribute the largest to the overall emissions profile for Hess TGP are the Clark compressor engines and the sulfur recovery unit operations.

Over the years of 2014–2018, the Clark compressor engines accounted for 91% of the facilities total NO_x emissions. A breakdown of the NO_x emissions profile can be found in Section 2.1.2.

Over the years of 2014–2018, the sulfur recovery operation accounted for 94% of the facilities total SO₂ emissions, where 79% of the total was from the tail gas incinerator. A breakdown of the SO₂ emissions profile can be found in Section 2.2.2.

The sulfur recovery unit tail gas incinerator has a SO₂ continuous emissions rate monitor system (CERMS) installed. The Clark compressor engines are tested semi-annually to ensure they are operating in compliance with the total tons of NO_x restriction in the facility's Title V Permit to Operate.

During the first round of the regional haze program, the Department determined that no NO_x or SO₂ controls were required the Hess TGP.¹

2.1 NO_x

2.1.1 NO_x Emissions Controls

A summary of the existing NO_x controls for the applicable Hess TGP emissions units are discussed in Section 2.1.1.1 and 2.1.1.2.

2.1.1.1 Clark Compressor Engines

Hess TGP operates seven Clark compressor engines, identified as C1A through C1G. These engines are fueled by a portion of the natural gas produced by the facility and are used to boost the pressure of the inlet field gas received for processing. All the Clark engines are lean burn integral engines, meaning the engine and compressor structure are a single unit, making it both difficult and costly to replace the units. Two of the engines (C1D and C1F) required modification in 2004, which entailed adding turbocharging systems. The turbocharging system significantly reduced NO_x emissions from these engines compared to the other five engines. The other five engines (C1A, C1B, C1C, C1E, and C1G) have not been significantly modified since construction in the 1950's but have been kept in good working order.² Feasible add-on controls for the remaining five engines are evaluated in Section 3.1. A discussion on the breakdown of emissions from these engines can be found in Section 2.1.2.

2.1.1.2 Remaining NO_x Emissions Units

Hess TGP does not operate any other units which are significant contributors of NO_x emissions, therefore, no additional equipment is evaluated for additional controls with this analysis. Hess TGP included an evaluation of NO_x controls on the sulfur recovery unit tail gas incinerator and considered the feasibility of a flare management plan to reduce emissions from this activity. Neither of these evaluations yielded any feasible controls.³

2.1.2 NO_x Emissions History

No recent NO_x controls have been installed at the facility, therefore, the baseline emissions from the facility were determined based on the average emissions from 2015–2018. This information is displayed in Table 2.

Table 2: Annual NO_x Emissions (tons)

Year	Clark Engines	Remaining Units ^A	Total
2015	1,366	106	1,472
2016	1,133	76	1,209
2017	535	93	627
2018	614	92	706
Average	912	92	1,004

^A Accounts for all other onsite emissions units.

¹ North Dakota State Implementation Plan for Regional Haze, March 3, 2010, p. 182-188.

² Appendix B.8.b., p. 11. PDF page 1386.

³ Appendix B.8.b, p. 28. PDF page 1403.

Given the magnitude of emissions produced from the Clark engines (91% of the facility total NO_x), they are the focus of determining the need for NO_x controls under the reasonable progress requirements. The NO_x emissions from the Clark Engines (Table 2), have been further separated by individual engines in Table 3 to show the variation between each engine and the impact the modification of C1D and C1F had on the NO_x emissions rate.

Table 3: Annual NO_x Emissions from Clark Engines (tons)

Year	C1A	C1B	C1C	C1E	C1G	C1D ^A	C1F ^A
2015	238	293	209	353	207	30	35
2016	171	215	255	257	150	25	30
2017	18	99	127	81	155	26	29
2018	107	148	139	0	186	19	16
Average	134	189	183	231	175	25	27

^A C1D and C1F were modified in 2004

Since each engine does not have the same operating hours per year, looking only at total emissions does not directly help with determining the best sources for individual controls. Therefore, the Department used the annual emissions (Table 3) and the annual operating hours (Table 4) to calculate the average pounds per hour of NO_x emissions from each engine (Table 5).

Table 4: Clark Engine Operation (hours)

Year	C1A	C1B	C1C	C1E	C1G	C1D	C1F
2015	6,520	7,749	5,818	7,437	7,885	8,314	8,568
2016	3,720	6,417	6,965	6,600	5,217	7,045	7,962
2017	528	3,506	4,258	2,070	6,240	8,165	6,708
2018	3,228	4,438	4,648	0	5,325	5,133	3,668
Average	3,499	5,528	5,422	5,369	6,167	7,164	6,727

Table 5: Non-modified Clark Engine NO_x Emissions (lb/hr)

Year	C1A	C1B	C1C	C1E	C1G
2015	73	76	72	95	53
2016	92	67	73	78	57
2017	66	56	60	78	50
2018	66	67	60	0	70
Average	75	66	66	84	57

Averaging the pound per hour data across the five non-modified Clark engines from Table 5, and pairing this with the average operating hours for the non-modified Clark engines (Table 4), yields a baseline emissions value of 181 tons per year from each of the five non-modified Clark engines. By chance, this happens to compare to the simple average of the five non-modified Clark engines, which is 182 tons per year.

181 tons per year of NO_x is used as the baseline rate for each non-modified Clark engine when evaluating the cost of additional controls in Section 3.2.

2.2 SO₂

2.2.1 SO₂ Emissions Controls

A summary of the existing SO₂ controls for the Hess TGP sulfur recovery process is discussed in Section 2.2.1.1.

2.2.1.1 Sulfur Recovery Process

The sulfur recovery process at Hess TGP consists of an amine gas sweetening unit and sulfur recovery unit (SRU). The SRU consists of a 2-stage Claus process followed by cold bed adsorption. Over the baseline years of 2015–2018 sulfur recovery has averaged 96%, see Table 6.

Table 6: Sulfur Recovery Process Data

Year	Sulfur Produced (Tons)	Sulfur from Tail Gas Incineration (Tons)	SRU Efficiency (%)
2015	8,968	307	96.7%
2016	8,029	241	97.1%
2017	8,167	359	95.8%
2018	8,243	497	94.3%
Average	8,352	351	96.0%

Remaining gas (tail gas) not converted to elemental sulfur during the reaction process is combusted in the tail gas incinerator. The tail gas incinerator accounted for an average of 79% of the facility SO₂ emissions (Table 7).

Another aspect of the sulfur recovery process produces SO₂ emissions is during acid gas flaring events. Acid gas produced by the amine sweetening unit feeds the sulfur recovery unit and acid gas flaring occurs when the sulfur recovery unit malfunctions and needs to be taken offline. Acid gas flaring is very intermittent, averaging 70 hours a year over the baseline years. This does, however, account for 15% of the facility SO₂ due to the high concentration of hydrogen sulfide in the acid gas. Since acid gas flaring is not a routine source of emissions, SO₂ reductions from this activity are not evaluated.

2.2.1.2 Remaining SO₂ Emissions Units

The only source of SO₂ emissions from the facility not associated with the sulfur recovery process come from the flaring of inlet (feedstock) gas. Hess TGP considered the feasibility of a flare management plan to reduce emissions from this activity.⁴ Since flaring only occurs during emergency events and other malfunctions related occurrences and is highly intermittent, a flare management plan was deemed unnecessary. Flaring accounts for approximately 6% of the SO₂ emissions over the baseline years, see Table 7.

2.2.2 SO₂ Emissions History

No recent SO₂ controls have been installed at Hess TGP, therefore, the baseline emissions from the facility were determined based on the average emissions from 2015–2018. This information is displayed in Table 7.

⁴ Appendix B.8.b, p. 15 and 30. PDF pages 1390 and 1405.

Table 7: Annual SO₂ Emissions (tons)

Year	Tail Gas Incineration	Acid Gas Flaring	Inlet Gas Flaring	Total
2015	614	178	114	906
2016	481	308	77	866
2017	719	29	2	749
2018	994	20	26	1,040
Average	702	134	55	890

As shown in Table 7, most of the SO₂ emissions from Hess TGP come from the incineration of the tail gas produced by the sulfur recovery unit. During normal operations, this is the only significant source of SO₂ emissions. Tail gas incineration accounts for an average of 79% of the facility SO₂ emissions. Acid gas flaring (15%) and inlet gas flaring (6%) account for the remaining portion of SO₂ emissions where controls could theoretically be evaluated. However, as both inlet and acid gas flaring are intermittent and not intended operations, controls are not evaluated from these sources.

3 NO_x Analysis

3.1 NO_x Technologies

The NO_x controls evaluated for the non-modified Clark engine are discussed in Sections 3.1.1 and 3.1.2.

3.1.1 Low-emission Controls (LEC)

LEC is a system of upgrades, modifications, and tuning on the Clark engines to achieve a lower emissions rate. LEC is anticipated to achieve 70-90% reduction in NO_x emissions and achieve a controlled emissions rate of 1 gram per brake horsepower hour, which is consistent with most new internal combustion engines.⁵ LEC installation on non-modified Clark engines is technically feasible and will be further evaluated.

3.1.2 Selective Catalytic Reduction (SCR)

SCR is an exhaust control that could be applied to lean combustion engines which reduces NO_x emissions by reacting NO_x with ammonia or urea over a catalyst.⁶ SCR is anticipated to achieve 70-90% reduction in NO_x emissions and achieve a controlled emissions rate of 1 gram per brake horsepower hour, the same rate which could be achieved through installation of LEC. Since LEC could achieve the emissions same rate as SCR with less impacts elsewhere, SCR will not be evaluated further. Additional impacts with SCR consist of multiple energy and non-environmental issues associated with installation and operation.⁷ While technically feasible, SCR is rarely used in the natural gas transmission and related industries, giving further support to remove this from further evaluation.⁸

⁵ Appendix B.8.b, p. 12. PDF page 1387.

⁶ Appendix B.8.b, p. 12. PDF page 1387.

⁷ Appendix B.8.b, p. 12-13 and 24. PDF page 1387-1388.

⁸ Appendix B.8.b, p. 13 and 29. PDF pages 1388 and 1404.

3.2 Step 1 – Cost of Compliance

The cost of compliance for the reasonable progress controls are listed in Table 8. These costs are for each individual non-modified Clark engines (C1A, C1B, C1C, C1E, and C1G). The costs have been determined on an average basis spread across each of the five engines due to the variability in each engines operation, as discussed in Section 2.1.2.

Table 8: NO_x Cost of Compliance for each non-modified Clark Engine

Control Technology	Annual Emissions (tpy)	Annual Emissions Reduction (tpy)	Annualized Total Cost (\$)	Cost of Compliance (\$/ton)
Baseline	181			
Low-Emissions Controls	36	145	1,271,977	8,784

A detailed breakdown of the costs listed in Table 8 can be found in Hess TGP's submitted four factors analysis.⁹ The Department has reviewed these costs and believes them to be accurate.

As displayed in Table 8, installation of LEC would reduce emissions by approximately 145 tons NO_x on each of the five non-modified Clark engines. This amounts to a combined total of 724 tons of NO_x from each non-modified engine. Individually, this reduction comes at a cost of approximately \$8,800 per ton of NO_x reduced at an annualized cost of approximately \$1.3 million. Installing LEC on each of these five engines amounts to a total annualized cost of roughly \$6.4 million.

3.3 Step 2 – Time Necessary for Compliance

Hess TGP indicated a timeline of five to seven years for installation of LEC on the non-modified Clark engines. This is due to the sequential order of installing controls to eliminate facility downtime.¹⁰ The time necessary for compliance is not a limiting factor when determining additional reasonable controls for the Hess TGP since LEC controls could be installed prior to the end of the second planning period.

3.4 Step 3 – Energy and Non-Air Quality Environmental Impacts

There are no energy or non-air quality environmental impacts associated with the installation of LEC on the non-modified Clark engines.

3.5 Step 4 – Remaining Useful Life

Hess TGP is expected to operate beyond the useful life of additional controls, therefore, remaining useful life is not a factor for consideration.

4 SO₂ Analysis

4.1 SO₂ Technologies

The SO₂ controls evaluated for the sulfur recovery process are discussed in Sections 4.1.1 through 4.1.3.

⁹ Appendix B.8.b., Appendix A. PDF page 1406

¹⁰ Appendix B.8.b., p. 21. PDF page 1396

4.1.1 Tail Gas Treatment

Tail gas treatment or tail gas scrubbing treatment (TGST) adds an additional scrubbing system on the exhaust of the current sulfur recovery unit prior to the tail gas incineration. There are many types of tail gas treatment options available, each of which serves a specific purpose or industry.¹¹

A TGST system reduces the amount of sulfur sent to the tail gas incinerator, thereby increasing the overall sulfur recovery efficiency by reducing the SO₂ emissions produced during tail gas incineration. LO-CAT® technology was chosen for evaluation as this technology is commonly associated with the natural gas industry.¹² The LO-CAT® removes H₂S from an acid gas (or SRU tail gas) stream and converts it to elemental sulfur, essentially supplementing the current sulfur production at the facility. LO-CAT® is expected to reduce an additional 90% sulfur beyond the existing sulfur recovery, increasing the overall sulfur recovery to greater than 99%. Additional tail gas scrubbing treatment is technically feasibility and will be evaluated further.

4.1.2 Flue Gas Desulfurization (FGD)

Flue gas desulfurization was briefly explored as an alternative control option for Hess TGP. There are multiple reasons why traditional flue gas desulfurization is not reasonable to implement for control of SO₂ emissions from a gas processing facility.¹³ Tail gas treatment and acid gas disposal options are more effective and have less disadvantages associated with implementation, therefore, FGD will not be carried forward for further evaluation.

4.1.3 Acid Gas Disposal Injection Well

As an alternative to additional tail gas treatment discussed in Section 4.1.1, Hess TGP evaluated the feasibility of installing an acid gas disposal (AGD) injection well. In lieu of additional tail gas scrubbing, an AGD injection well can dispose of the tail gas produced by the SRU, eliminating the emissions associated with tail gas incineration. Infrastructure requirements and geological uncertainty both pose significant risk associated with implementation of an AGD injection well.¹⁴ Nevertheless, AGD is technically feasible and will be evaluated further.

4.2 Step 1 – Cost of Compliance

The cost of compliance for the reasonable progress controls evaluated for the sulfur recovery process are listed in Table 9. These costs are for the SO₂ controls deemed technically feasible.

Table 9: SO₂ Cost of Compliance for the Sulfur Recovery Process

Control Technology	Annual Emissions (tpy)	Annual Emission Reduction (tpy)	Annualized Total Cost (\$)	Cost of Compliance (\$/ton)
Baseline (96% recovery)	702			
Tail Gas Treatment	70	632	7,151,657	11,321
Acid Gas Disposal Injection Well	7	695	2,256,837	3,248
Acid Gas Disposal Injection Well ^A	7	695	3,087,549	4,443

¹¹ Appendix B.8.b., p. 6-8. PDF page 1381-1383

¹² Appendix B.8.b., p. 7. PDF page 1382

¹³ Appendix B.8.b., p. 8-9 and 28. PDF pages 1383-1384 and 1403.

¹⁴ Appendix B.8.b., p.10, 18-19, and 23. PDF pages 1385, 1393-1394, and 1398.

Control Technology	Annual Emissions (tpy)	Annual Emission Reduction (tpy)	Annualized Total Cost (\$)	Cost of Compliance (\$/ton)
--------------------	------------------------	---------------------------------	----------------------------	-----------------------------

^A Includes redundant compressor and plumbing costs

A detailed breakdown of the costs listed in Table 9 can be found in Hess TGP's submitted four factors analysis.¹⁵ The Department has reviewed these costs and believes them to be reasonably accurate. As indicated in the submitted report, the AGD injection well costs provided are expected to increase significantly if a further detailed evaluation is required.¹⁶ The cost of compliance for AGD injection well can be thought of as the very minimum cost for implementing this technology.

If a tail gas treatment system is installed, such as the LO-CAT® technology, a 90% reduction from the current SO₂ emissions can be achieved. This equates to a reduction of 632 tons SO₂ per year from the baseline emissions. Fiscally, tail gas treatment system comes at an estimated annualized cost of approximately \$7,152,000 and SO₂ removal cost of roughly \$11,300 per ton.

If an AGD injection well is installed, 99% of the current SO₂ emissions from the current SRU process will be eliminated. This equates to a reduction of 695 tons SO₂ per year from the baseline emissions. Fiscally, AGD requires an estimated annualized cost of approximately \$2,257,000 and SO₂ removal cost of roughly \$3,250 per ton.

As mentioned in Table 9, if redundant AGD equipment is installed, the estimated annualized cost increases to approximately \$3.1 million and SO₂ removal cost increases to roughly \$4,400 per ton. Redundant AGD equipment would be utilized to dispose the acid gas in the event when a malfunction occurs. These malfunctions are generally unplanned, short duration-episodes (a few hours) with very high SO₂ emission rates that vary from year-to-year. Without redundancy, controlling emissions during malfunctions is not feasible and the acid gas is flared to prevent the release of high concentrations of H₂S, negating the benefit of injecting the gas underground.

4.3 Step 2 – Time Necessary for Compliance

Hess TGP indicated a timeline of four to five years for installation and operation of a LO-CAT® unit.¹⁷ Construction and operation of an AGD injection well was estimated at a minimum of five years. This estimate is highly uncertain given all the variables associated with installation.¹⁸ The variables, such as equipment procurement, land surveying and acquisition, permitting, sub-surface research, and pipeline construction, would also likely add significant unforeseen expenses. The time necessary for compliance is not a limiting factor when determining additional reasonable controls for the Hess TGP since the projects could likely be completed prior to the end of the second-round planning period or an agreed upon schedule could be negotiated between the Department and Hess TGP.

¹⁵ Appendix B.8.b., p. Appendix A. PDF page 1406

¹⁶ Appendix B.8.b., p.18-19. PDF page 1939-1394.

¹⁷ Appendix B.8.b., p. 21. PDF page 1396.

¹⁸ Appendix B.8.b., p. 21-22. PDF page 1396-1397.

4.4 Step 3 – Energy and Non-Air Quality Environmental Impacts

Hess TGP's submitted four factors analysis indicated various energy and non-air quality environmental impacts from the LO-CAT® unit ranging from increased electrical demand to spent catalyst disposal.¹⁹ While these impacts can be significant, none of the impacts eliminate the LO-CAT® as a potential add-on control option.

Hess TGP's four factor analysis also indicated various energy and non-air quality environmental impacts from the AGD injection well. Risks associated with construction and operation of the AGD pipeline are potentially significant and AGD also generates a new waste stream from the compression and dehydration of the acid gas.²⁰ Additionally, a considerable amount of electricity is required for the operation of the AGD equipment. While these impacts can be significant, none of the impacts eliminate an AGD injection well as a potential add-on control option.

4.5 Step 4 – Remaining Useful Life

Based on the information provided to the Department, Hess TGP is expected to operate beyond the life of the control equipment. Therefore, remaining useful life was not considered.

¹⁹ Appendix B.8.b., p. 23. PDF page 1398.

²⁰ Appendix B.8.b., p. 23. PDF page 1398.

A.9 – Northern Border CS4

1 Introduction and Representative Operations

Northern Border Pipeline Company (NBPC) – Compressor Station No. 4 (CS4) is a compressor station with the majority of emissions being sourced from a 20,000 horsepower simple cycle natural gas-fired combustion turbine (Unit CE1), which drives a natural gas compressor. The turbine is a Cooper-Rolls Model Coberra 2648S Avon. CS4 is located approximately nine miles west of Watford City, North Dakota in McKenzie County.

Data from 2012–2018 was used to when determining representative operations for the facility. 2012–2018 was chosen since this seven-year timeframe captured two high utilization years, two low utilization years, and three moderate utilization years. The yearly data is displayed in Table 1. Utilization was calculated by taking the annual actual hours of operation divided by total hours in a year (8760 hours per year).

Table 1: Yearly Operational Data

Year	Operating Time (hrs)	Yearly Duty (MMBtu/yr)	Utilization
2012	8,494	1,262,480	97%
2013	8,346	1,328,516	95%
2014	4,116	594,188	47%
2015	3,713	499,517	42%
2016	7,161	1,052,922	82%
2017	6,822	1,048,291	78%
2018	6,909	983,570	79%
Average	6,509	967,069	74%

Based on the information provided to the Department by NBPC, CS4's recent averaged operational data, Table 1, is consistent with anticipated future operations.¹

2 NO_x Emissions Controls and Representative History

During the first round of the regional haze program, the Department determined that NBPC – CS4 was eliminated from consideration of additional controls. This was due to the average 2006–2008 NO_x plus SO₂ emissions being 118 tons per year, resulting in a Q/d of 6.6 (118 tons/18 km = 6.6).² The focus of this determination is on NO_x emissions. CS4 combusts pipeline quality natural gas, therefore, SO₂ emissions were not considered when reviewing emissions control options.

2.1 NO_x

2.1.1 NO_x Emissions Controls

There have been no upgrades or retrofits installed on CS4's 20,000 horsepower existing turbine. Additionally, there are no existing add-on NO_x controls installed on the turbine.

¹ Appendix B.9.b., p.2. PDF page 1457.

² North Dakota State Implementation Plan for Regional Haze, March 3, 2010, p. 180.

2.1.2 NO_x Emissions History

Consistent with operational data displayed Table 1, 2012–2018 was the time period used to determine the NO_x baseline emissions for CS4. This information is displayed in Table 2.

Table 2: NO_x Emissions

Year	Representative Emissions Rate (lb/MMBtu) ^A	Emissions Rate (lb/hr)	Calculated NO _x Emissions (tpy)
2012	0.27	40.3	171
2013	0.27	43.1	180
2014	0.27	39.1	80
2015	0.27	36.5	68
2016	0.27	39.8	143
2017	0.27	41.6	142
2018	0.27	38.6	133
Average	0.27	39.9	131

^A Average tested emission rate from testing completed from 2012-2018.

The representative emissions rate (lb/MMBtu) was calculated from an average of 11 tests over the 7 years. These tests are considered representative of typical operations and anticipated future operations. Load during testing ranged from 58% to 95%, with an average of 81%. Emissions rates varied from 0.21 to 0.33 lb/MMBtu, with an average of 0.27 lb/MMBtu.³ The value of 0.27 lb/MMBtu is used as the starting point when determining the cost of compliance for add-on controls evaluated in 3.2.

3 NO_x Four-Factor Analysis

3.1 NO_x Technologies Evaluated

The turbine manufacturer does not offer a burner retrofit option for lean premixed combustion, therefore, only add-on NO_x controls were evaluated. Of the add-on control, selective catalytic reduction and water injections were reviewed.

Water injection is a control technology which has the potential to decrease NO_x emissions by decreasing the peak flame temperature in the turbine. Water injection is an older technology which has fallen out of favor since low emission combustion controls and/or SCRs have been refined and implemented. Factors which limit the feasibility of water injection are increased carbon monoxide emissions, heat rate penalty, and potential for flame blow-off or flame-out. The issues are significant enough to eliminate water injection as a potential NO_x control option.

The reasonable progress controls evaluated by NBPC and determined to be available and technically feasible are listed in Table 3. Performance rate and expected annual emissions are included for each control technology that was determined to be technically feasible. Expected annual emissions were calculated using the performance rate and the average yearly duty (Table 1).

³ Appendix B.9.c., PDF page 1471.

Table 3: Reasonable Progress NO_x Controls

Control Technology	Control Technology Abbreviation	Performance Rate (lb/MMBtu)	Emissions (tons/year)
Uncontrolled (baseline)	--	0.27	131
selective catalytic reduction	SCR	0.05	26

3.1.1 Selective Catalytic Reduction (SCR)

Selective catalytic reduction (SCR) is an add-on control technology used to reduce NO_x emissions after formation during the combustion process. SCR is a well understood technology that has been implemented on many different combustion processes. SCR is anticipated to provide an approximately 80% reduction in NO_x emissions from the baseline scenario, lowering the expected performance from 0.27 to 0.05 lb NO_x per MMBtu. SCR is technically feasible and will be further evaluated.

3.2 Step 1 – Cost of Compliance

The cost of compliance for the reasonable progress controls are listed in Table 4.

Table 4: NO_x Cost of Compliance

Control Technology	Performance Rate (lb/MMBtu)	Annual Emission Reduction (tpy)	Annualized Total Cost (\$)	Cost of Compliance (\$/ton)
Uncontrolled (baseline)	0.27			
selective catalytic reduction	0.05	105	1,374,201	13,040

A detailed breakdown of the costs listed in Table 4 can be found in NBPC's submitted four factors analysis.⁴ The Department has reviewed these costs and believes them to be accurate.

If SCR is installed, a performance rate improvement of 0.22 lb NO_x per MMBtu could be achieved. This equates to a potential reduction of 105 tons NO_x per year from the baseline emissions. Fiscally, SCR installation requires an estimated annualized cost of \$1.4 million and NO_x removal cost of \$13,000 per ton.

3.3 Step 2 – Time Necessary for Compliance

Installation of SCR would require at least 36 months to complete.⁵ The time necessary for compliance is not a limiting factor when determining additional reasonable controls for NBPC – CS4 since it could be installed prior to the end of the second planning period.

⁴ Appendix B.9.b., PDF page 1459.

⁵ Appendix B.9.b., p.3. PDF page 1458.

3.4 Step 3 – Energy and Non-Air Quality Environmental Impacts

3.4.1 Energy and Non-Air Quality Environmental Impacts

NBPC's submitted four factors analysis indicated various energy and non-air quality environmental impacts ranging from increased electrical demand to ammonia slip emissions.⁶ While these impacts can be significant, none of the impacts eliminate SCR as a potential add-on control option.

3.5 Step 4 – Remaining Useful Life

Based on the information provided to the Department, the turbine at CS4 is expected to operate beyond the life of the control equipment.⁷ Therefore, remaining useful life was not considered.

⁶ Appendix B.9.b., p.3. PDF page 1458.

⁷ Appendix B.9.b., p.4. PDF page 1459.

A.10 – Basin DGC

1 Introduction and Representative Operations

Dakota Gasification Company (DGC) – Great Plains Synfuels Plant (GPSP) is owned and operated by Bain Electric Power Cooperative (Basin). DGC is a for-profit subsidiary of Basin and produces synthetic natural gas, fertilizers, and other byproducts resulting from the gasification of lignite coal. GPSP also captures carbon dioxide, which is transported via pipeline to oil fields in Saskatchewan Canada. The GPSP is the only facility of its kind in the United States. The GPSP commenced operation in 1984. The GPSP consists of many emissions units and emissions points. The significant sources of NO_x and SO₂ emissions include:

- Three Riley boilers each rated at 763 MMBtu per hour
- Two superheaters each rated at 169 MMBtu per hour
- One package boiler rated at 318 MMBtu per hour
- The main flare and the start-up flare

The DGC GPSP is located approximately six miles northwest of the town of Beulah, North Dakota in Mercer County. The GPSP receives lignite coal from the Coteau Properties Freedom Mine located approximately two miles north of the GPSP. Coal which is too fine for gasification is sent back to the Antelope Valley Station (AVS) electrical generating utility (EGU).

The average annual amount of North Dakota lignite gasified from 2014 through 2018 was approximately 6.1 million tons. The amount of coal gasified at the GPSP does not directly correlate with the emissions from the facility but helps show consistent operations over the recent years from the facility. With this consistent operation, emissions from this time period can be averaged to determine representative baseline emissions in order to evaluate additional feasible controls. See Table 1 for detailed information.

Table 1: Annual Coal Consumed (tons)

Year	Gasifier Feed (tons)
2014	6,071,536
2015	6,207,012
2016	5,998,365
2017	6,047,430
2018	6,186,391
Average	6,102,147

Representative operations for the Riley boilers and Superheaters are based on the recent emissions from the units versus the amount of fuel consumed due to the variety of fuels these unit combust and varying heat content of the fuels. The Riley Boilers are designed to burn a combination of gasification products, including liquid and gaseous fuels consisting of waste gas, stink gas, tar oil, naphtha/phenol (N/P) blend, lock gas, medium BTU purge gas, and SNG. The Superheaters are designed to combust SGN and/or tar oil; typically firing 80-90% SNG. The Riley Boilers and the Superheaters share a common stack (Main Stack), where the Superheaters' flue gas is combined

with the Riley Boilers' flue gas downstream of the Riley Boilers wet flue gas desulfurization (WFGD) system.

The Package Boiler was installed in 2017 to support the operation of the urea production facility and is fired strictly on natural gas. The Package Boiler flue gas is directed through the facility Bypass Stack. The Bypass Stack also handles the flue gas from the Main Stack (Riley Boilers and Superheaters) when the WFGD system is down.

The Main Flare is the primary control device and operates during upsets to control volatile process gases. The Start-up Flare is used during start-up, shutdowns, and gasifier malfunctions. Neither the Main Flare nor the Start-up Flare is indented to operate consistently; therefore, they will not be evaluated for additional controls.

2 NO_x and SO₂ Emissions Controls and Representative History

Both the Main Stack and the Bypass have NO_x and SO₂ continuous emissions monitor systems (CEMS) installed. The Main Stack CEMS monitors the routine emissions from the Riley Boilers and Superheaters. The Bypass Stack CEMS monitors the routine emissions from the Package Boiler and malfunction (bypass of WFGD) emissions from the Riley Boilers and Superheaters.

During the first round of the regional haze program, the Department determined that no NO_x or SO₂ controls were required the GPSP.¹

2.1 NO_x

2.1.1 NO_x Emissions Controls

A summary of the existing NO_x controls for the applicable GPSP emissions units are discussed in Section 2.1.1.1 through 2.1.1.4.

2.1.1.1 *Riley Boilers*

The existing NO_x controls on the Riley Boilers consists of Low-NO_x burners (LNB), Overfire Air, and combustion tuning. No add-on NO_x controls are installed on the Riley Boilers. Feasible add-on controls are evaluated in Section 3.1.

2.1.1.2 *Superheaters*

The existing NO_x controls on the Superheaters consist of LNB, partial flue gas recirculation (FGR), and combustion tuning. No add-on NO_x controls are installed on the Superheaters. Feasible add-on controls are evaluated in Section 3.1.

2.1.1.3 *Package Boiler*

The existing NO_x controls on the Package Boiler consist of Ultra LNB (ULNB). No add-on NO_x controls are installed on the Package Boiler. Add-on controls for the Package Boiler were not evaluated. Operation of ULNB is considered Best Available Control Technology (BACT) for units of similar size combusting natural gas. The Package Boiler currently achieves a NO_x rate of approximately 30 parts per million by volume dry (ppmvd) and is expected to continue to achieve this rate.²

¹ North Dakota State Implementation Plan for Regional Haze, March 3, 2010, p. 182-188.

² Appendix B.10.b., p.7-1. PDF page 1527

2.1.1.4 Main Flare and Start-up Flare

The Main Flare and the Start-up Flare have no existing NO_x controls installed. The GPSP evaluated potential options for mitigating NO_x emissions from the flared process gases. No vendors were able to provide any viable solutions to reduce NO_x emissions from the either flare system, mainly due to the low baseline NO_x value, equivalent to approximately 0.06 lb NO_x per MMBtu.³

2.1.2 NO_x Emissions History

No recent NO_x controls have been installed at any facility, therefore, the baseline emissions from the facility were determined based on the average emissions from 2014–2018. This information, displayed by emissions point, is shown in Table 2.

Table 2: Annual NO_x Emissions

Year	Main Stack	Bypass Stack	Main Flare	Start-up Flare	Remaining Sources ^A	Total
2014	3,048	91	55	12	29	3,236
2015	2,777	49	105	12	40	2,982
2016	2,346	32	43	8	25	2,454
2017	2,373	120	54	10	23	2,580
2018	2,305	45	46	9	31	2,437
Average	2,570	67	61	10	30	2,738

^A Accounts for all other onsite emissions units.

As shown in Table 2, most of the NO_x emissions from GPSP come from the Main Stack. During normal operations, the Main Stack receives flue gas from the Riley Boilers and the Superheaters. The Main Stack accounts for an average of 94% of the facility NO_x emissions. The Bypass stack accounts for the remaining portion of NO_x emissions where controls can be evaluated. The Bypass Stack only receives gas from the Package Boiler during normal operations and the Package Boiler has ULNB installed, therefore, evaluation of additional controls is focused on Riley Boilers and the Superheaters.

2.2 SO₂

2.2.1 SO₂ Emissions Controls

A summary of the existing SO₂ controls for the applicable GPSP emissions units are discussed in Section 2.2.1.1 through 2.2.1.4.

2.2.1.1 Riley Boilers

The existing SO₂ controls on the Riley Boilers consists of a wet flue gas desulfurization (WFGD) system. The WFGD system is designed to treat 100% of the Riley Boiler flue gas during normal operations and often operates at a 97-98% SO₂ removal efficiency.⁴ During the first-round planning period, the Department concluded that this system is comparable to BACT for this process and no additional controls were recommended.⁵ There have been no significant improvements in available

³ Appendix B.10.b., p.8-2. PDF page 1529.

⁴ Appendix B.10.b., p.5-1. PDF page 1509.

⁵ North Dakota State Implementation Plan for Regional Haze, March 3, 2010, p. 183

SO₂ controls for the Riley Boilers WFGD system, therefore, further SO₂ reductions from this source cannot be evaluated.

2.2.1.2 Superheaters

The Superheaters have no existing SO₂ controls installed. The Superheaters typically fire between 80-90% SNG, with the balance being tar oil. SNG is an inherently low sulfur fuel. The SO₂ emissions from the Superheaters come from the firing of tar oil. Given most of the Superheaters heat input comes from firing of SNG, the only potentially viable way to reduce SO₂ from this source would be to eliminate firing of tar oil in the superheaters. Retaining the flexibility to fire tar oil in the Superheaters is essential to provide process relief during unexpectedly high tar oil production rates or high accumulation rates.⁶ GPSP currently minimizes the SO₂ emissions attributable to the Superheaters by mainly firing SNG. As a result, no feasible control options exist to reduce SO₂ emissions resulting from the Superheaters.

2.2.1.3 Package Boiler

The Package Boiler fires SNG, an inherently low sulfur fuel. Therefore, no SO₂ control evaluated is warranted on this unit.⁷

2.2.1.4 Main Flare and Start-up Flare

The Main Flare and the Star-up Flare have no existing SO₂ controls installed. The GPSP evaluated flare gas scrubbing as a potential option for mitigating SO₂ emissions from the flared process gases. It was determined that, at a minimum, pilot scale testing would be needed to evaluate the effectiveness of the scrubbing.⁸ This source also accounts for a small percentage (8%) of the facilities SO₂ emissions, therefore, this source will not be further evaluated.

2.2.2 SO₂ Emissions History

No recent SO₂ controls have been installed at any facility, therefore, the baseline emissions from the facility were determined based on the average emissions from 2014–2018. This information, displayed by emissions point, is shown in Table 3.

Table 3: Annual SO₂ Emissions

Year	Main Stack	Bypass Stack	Main Flare	Start-up Flare	Remaining Sources ^A	Total
2014	1,922	1,347	467	82	0	3,818
2015	2,211	794	212	74	2	3,294
2016	3,063	378	212	22	1	3,677
2017	2,742	2,152	284	24	0	5,203
2018	2,139	310	369	14	0	2,832
Average	2,415	996	309	43	1	3,765

^A Accounts for all other onsite emissions units.

As shown in Table 3, most of the SO₂ emissions from GPSP come from the Main Stack. During normal operations, the Main Stack receives flue gas from the Riley Boilers and the Superheaters. The Main

⁷ Appendix B.10.b., p.7-1. PDF page 1527

⁸ Appendix B.10.b., p.8-1 and 8-2. PDF page 1527-1528

Stack accounts for an average of 64% of the facility SO₂ emissions. The Bypass stack accounts for the remaining portion of SO₂ emissions where controls can be evaluated, as scrubbing of the flare gas was determined technically infeasible. During normal operations, the Bypass Stack only receives flue gas from the Package Boiler and the Package Boiler fires inherently low sulfur fuel (SNG). As displayed in Table 3, the majority of SO₂ emissions from the Bypass Stack occur when the Riley Boilers WFGD system malfunctions and the flue gas needs to be routed to the uncontrolled Bypass Stack.

As stated in Section 2.2.1.1, the Riley Boilers are controlled by a WFGD system operating at BACT levels.

3 NO_x Analysis

3.1 NO_x Technologies

Additional NO_x controls have been evaluated for the Riley Boilers and the Superheaters at the GPSP.

3.1.1 Combustion Optimization

Combustion optimization was evaluated as a control option to reduce NO_x emissions through implementation of on-line combustion optimization concepts, such as neural networks. Combustion optimization on the Riley Boilers is technical infeasible due to the variety of fuels consumed in the Riley Boilers and the flexibility needed for steam production rates at pressures, flow rates, and qualities.⁹ Combustion optimization on the Superheaters is technically feasible, but expected to only reduce 10 tons of NO_x on an annual average.¹⁰ Combustion optimization will not be evaluated any further given the insignificant improvement on the Superheaters and technical infeasibility on the Riley Boilers.

3.1.2 Flue Gas Recirculation

Flue gas recirculation was evaluated as a potential control option to reduce NO_x emissions at the Riley Boilers. The Riley Boilers currently fire waste gas (as one of the fuels), which contains a significant percentage of inert compounds (CO₂). The high amount of inert compound results in similar combustion flame temperatures and oxygen content as traditional flue gas recirculation. Therefore, any additional flue gas recirculation is not technically feasible for implementation.¹¹

3.1.3 Selective Non-Catalytic Reduction

Selective non-catalytic reduction (SNCR) was evaluated as a control option to reduce NO_x emissions from the Riley Boilers and Superheaters. Implementation of SNCR on the Riley Boilers was deemed technically infeasible during the first-round planning period and no new developments have occurred which changes this determination.¹² Similar to the Riley Boilers, installation of SNCR on the Superheaters is not technically feasible. This is due to the low reheat duct temperatures and the presence of sulfur in the fuel which will lead to the formation of ammonia salts which will foul the superheaters reducing their efficiency.

⁹ Appendix B.10.b, p.5-3. PDF page 1511.

¹⁰ Appendix B.10.b, p.9-4. PDF page 1534.

¹¹ Appendix B.10.b, p.5-4. PDF page 1512.

¹² North Dakota State Implementation Plan for Regional Haze, March 3, 2010, p. 184.

3.1.4 Selective Catalytic Reduction

Selective catalytic reduction (SCR) was evaluated as a control option to reduce NO_x emissions from the Riley Boilers and Superheaters. Implementation of SCR on the Riley Boilers was deemed technically infeasible during the first-round planning period and no new developments have occurred which changes this determination.¹³ Similar to the Riley Boilers, installation of SCR on the Superheaters is not technically feasible. This is due to the introduction of vapor phase alkali metals which degrade the SCR catalyst.¹⁴

3.2 Step 1 – Cost of Compliance

All NO_x controls evaluated are considered technically infeasible by the Department, therefore, no cost analysis is required to be completed. Since there was uncertainty in first-round planning period regarding the implantation of SCR on the Riley Boilers, GPSP performed a cost analysis on what tail-end SCR would cost and how much NO_x emissions would be reduced. GSPS estimated they could reduce approximately 1,800 tons of NO_x emissions from the Riley Boilers at a cost effectiveness of roughly \$39,000 per tons of NO_x reduced. This comes at a total capital cost of approximately \$180 million and an annualized cost of \$70 million.

3.3 Step 2 – Time Necessary for Compliance

The time necessary for compliance is not considered since no feasible NO_x controls can be installed.

3.4 Step 3 – Energy and Non-Air Quality Environmental Impacts

The energy and non-air quality environmental impacts are not considered since no feasible NO_x controls can be installed.

3.5 Step 4 – Remaining Useful Life

The remaining useful life is not considered since no feasible NO_x controls can be installed.

4 SO₂ Analysis

There are no additional reasonable controls which could be installed at GPSP. As stated in Section 2.2.1.1, the Riley Boilers currently operate a WFGD comparable to BACT. As stated in Section 2.2.1.2, the Superheaters primarily fire inherently low natural gas and need to maintain the flexibility to combust tar oil to provide process relief during expected tar oil production rates or system build-up.

Since there are no feasible SO₂ controls being carried forward for evaluation, the cost of compliance, time necessary for compliance, energy and non-air quality environmental impacts, and remaining useful life were not evaluated.

Re: Regional Haze
Second Planning Period

Dear Mr. Thoma:

The Department of Health (Department) has begun work on the second planning period (Round 2) State Implementation Plan (SIP) for regional haze. In Round 1 of the regional planning process, the emphasis was on Best Available Retrofit Technology (BART) and making reasonable progress towards the national visibility goal. In Round 2, there are no BART requirements; therefore, we will focus on making reasonable progress. The reasonable progress analysis will be made using the four factors in Section 169A(g)(1) of the Clean Air Act:

The four factors are:

1. The cost of compliance
2. The time necessary to achieve compliance
3. The energy and non-air quality environmental impact of compliance; and
4. The remaining useful life of any existing source subject to such requirements

Guidance provided by the U.S. Environmental Protection Agency (Draft Guidance on Progress Tracking Metrics, Long Term Strategies, Reasonable Progress Goals and Other Requirements for Regional Haze State Implementation Plans for the Second Implementation Period at https://www.epa.gov/sites/production/files/2016-07/documents/draft_regional_haze_guidance_july_2016.pdf) indicates the Department must address 80% of the visibility impairment caused by in-state sources. Data from the IMPROVE monitoring sites at Theodore Roosevelt National Park (TRNP) and Lostwood Wilderness Area (LWA) indicate that sulfates and nitrates continue to be the largest contributors to visibility impairment in these areas. The primary precursors of sulfates and nitrates are emissions of sulfur dioxide (SO₂) and nitrogen oxides (NO_x).

Coal-fired electrical generating units have been identified as one of the largest source of sulfur dioxide and nitrogen oxides in North Dakota. Therefore, the Department requests that you prepare a "four factors" analysis for your coal-fired electrical generating units. The analysis should be prepared using the draft EPA guidance noted above. The Department will identify other sources in North Dakota that will be required to submit a four factors analysis.

The Department will be working with the Western Regional Air Partnership (WRAP) to prepare the Round 2 SIP. WRAP will be conducting air quality modeling of regional emissions reductions in early 2019. The Department asks that your "four factors" analysis be submitted by January 31, 2019.

If you have any questions, please contact David Stroh of my staff at (701)328-5188.

Sincerely,

Terry L. O'Clair
Director
Division of Air Quality

Dear Mr. O'Clair:

Re: Regional Haze Second Planning Period: Coyote Station Reasonable Progress Analysis

As requested by your letter dated May 2, 2018, enclosed is a Regional Haze reasonable progress analysis for Coyote Station. Sargent & Lundy, L.L.C. was retained to prepare this analysis of technically feasible sulfur dioxide and nitrogen oxide emission reduction measures using the four statutory factors provided in Section 169A(g)(1) of the Clean Air Act.

As noted in the report, this analysis is subject to several important caveats and limitations, including but not limited to:

- On September 11, 2018, EPA released a "*Regional Haze Reform Roadmap*" announcing its plan to "release a series of implementation tools and guidance documents that will help focus states' efforts and reduce and streamline the time and resources needed to meet the statutory and regulatory requirements for reducing regional haze in National Parks, wildlife refuges, and wilderness areas." EPA stated that it plans to issue new guidance on Regional Haze SIP Development by Spring 2019. Otter Tail reserves the right to update and modify this four-factor analysis, as needed, to be consistent with any new guidance issued by EPA.
- The emission rates that are presented for the technically feasible control options should not be construed to represent proposed permit limits. Corresponding permit limits would need to be evaluated on a control system-specific basis to account for operating margin.
- During the first planning period, the Department of Health determined that high-dust SCR and tail-end SCR were not available, and thus, not a technically feasible NOx control option for North Dakota lignite-fired boilers. Sargent & Lundy's evaluation continues to support the conclusion that high-dust SCR and tail-end SCR are not available NOx control technologies. Nevertheless, since tail-end SCR cost data was developed for Coyote Station in the first planning period, even though tail-end SCR is a technically infeasible technology, it was carried forward in the analysis to evaluate hypothetical cost-effectiveness.

We look forward to working with the Department throughout the second planning period. If you have any questions about this report, please contact me at (218) 739-8526.

Sincerely,

EXECUTIVE SUMMARY

Coyote Station, located near Beulah, ND, commenced commercial operation in 1981. The facility is a single unit station with one 451 MWg (approximate) Babcock and Wilcox cyclone boiler (Coyote Unit 1). Coyote Unit 1 is designed to fire North Dakota lignite, and is equipped with separated overfire air (SOFA) for NO_x control, and dry flue gas desulfurization (DFGD or dry FGD) and fabric filter baghouse (FF) for SO₂ and particulate matter (PM) control. Lignite is delivered to the Station from the Coyote Creek Mine, whose primary operations are approximately 3-4 miles from the Coyote Station.

On July 1, 1999, the U.S. Environmental Protection Agency (EPA) published regulations implementing Section 169A of the CAA, establishing a comprehensive visibility protection program for Federal Class I areas (the Regional Haze Rule).¹ The Regional Haze Rule requires each state to develop, and submit for approval by EPA, a state implementation plan (SIP) detailing the state's plan to protect visibility in Class I areas. The Regional Haze Rule established a schedule setting forth deadlines by which the States must submit their initial regional haze SIPs and subsequent revisions to the SIPs. Regional Haze SIPs for the initial planning period were due in 2007, with subsequent SIP updates due in 2018 and every 10 years thereafter.² Second planning period Regional Haze SIPs must be submitted to EPA for review by July 31, 2021.

As part of North Dakota's SIP development for the second planning period, NDDH requested that Otter Tail prepare a "four factor" analysis for Coyote Unit 1. This evaluation reviews technically feasible SO₂ and NO_x emissions reduction measures for the following four statutory factors:

1. The costs of compliance;
2. The time necessary for compliance;
3. The energy and non-air quality environmental impacts of compliance; and
4. The remaining useful life of any potentially affected anthropogenic source of visibility impairment.

Technically feasible SO₂ and NO_x control strategies for Coyote Unit 1 are included in Table ES-1 and Table ES-2. The tables also show baseline emission rates and estimated emission reductions for each control option.

¹ 64 FR 35713

² On January 10, 2017, EPA made a one-time adjustment to the due date for the second implementation period SIPs (2018 – 2028) by extending the deadline from July 31, 2018 to July 31, 2021 (82 FR 3078).

Table ES-1. SO₂ Control Options for Coyote Unit 1

Control Option	SO ₂ Emission Rate tons/yr	% Reduction from Baseline Emission Rate
Baseline (existing DFGD/FF)	12,994	-
DSI + Existing FGD	8,863	32%
FGD Operational Improvements – Increase Ca:S Stoichiometric Ratio	7,641	41%
DSI + FGD Operational Improvements	5,043	61%
FGD Upgrades - Replacing Existing Absorbers with New Absorber	4,432	66%
Dry FGD (CDS) + Existing FF	1,375	89%
Wet FGD	917	93%

Table ES-2. NO_x Control Options for Coyote Unit 1

Control Option	NO _x Emission Rate tons/yr	% Reduction from Baseline Emission Rate
Baseline (existing SOFA)	7,363	-
Combustion Optimization	6,775	8%
SNCR + Combustion Optimization	4,516	39%
SNCR + RRI + Combustion Optimization	3,226	56%
SCR – Tail-End Configuration ^(Note 1)	1,452	80%

Note 1. Tail-end SCR has not been installed on a North Dakota lignite-fired unit, and extended trials would be needed to better understand the design and operation of tail-end SCR on Coyote Unit 1. Nevertheless, during the initial planning period, tail-end SCR was included in the reasonable progress analysis for Coyote Unit 1, and evaluated the costs and cost-effectiveness of the control system. For consistency with the first planning period, tail-end SCR is carried forward to the Four Factor Analysis.

Costs of Compliance (Statutory Factor One)

Capital and O&M cost estimates were developed for each of the technically feasible SO₂ and NO_x control options. The Coyote Unit 1 cost estimates are conceptual in nature; thus, S&L did not procure equipment quotes specifically for the Unit 1 control system upgrades. Rather, equipment costs are based on conceptual designs developed for the retrofit control systems, preliminary equipment sizing developed for the major pieces of equipment (based on

Coyote Unit 1-specific design parameters, including typical fuel characteristics, full load heat input, and flue gas temperatures and flow rates), and recent pricing for similar equipment.

Table ES-3 and Table ES-4 include estimated costs for SO₂ and NO_x control options for Coyote Unit 1. The tables provide the estimated annualized capital and operating and maintenance (O&M) costs, estimated emissions reductions, average annual cost effectiveness. The tables also include the incremental cost effectiveness that compares the costs and performance of a control option to those of the next most stringent option.

Table ES-3. SO₂ Emissions Control System Cost Effectiveness (\$2018)

SO ₂ Control Option	Total Annualized Cost \$/yr	Expected Emission Reduction tons SO ₂ /yr	Average Annual Cost Effectiveness (Note 1) \$/ton SO ₂ removed	Incremental Annual Cost Effectiveness (Note 2, 3) \$/ton SO ₂ removed
Baseline (Existing DFGD/FF)	---	---	---	---
DSI + Existing FGD	\$14,277,000	4,131	\$3,456	
FGD Operational Improvements – Increase Ca:S Stoichiometric Ratio	\$2,492,000	5,354	\$465	n/a
DSI + FGD Operational Improvements	\$16,770,000	7,952	\$2,109	\$5,496
FGD Upgrades - Replacing Existing Absorbers with New Absorber	\$22,197,000	8,563	\$2,592	\$8,879
Dry FGD (CDS) + Existing FF	\$42,246,000	11,619	\$3,636	\$6,560
Wet FGD	\$49,614,000	12,078	\$4,108	\$16,072

Note 1. Average cost effectiveness for each control option is the total annual cost divided by the expected emission reduction.

Note 2. Incremental cost effectiveness represents the incremental increase in annual costs (\$/yr) divided by the incremental increase in annual emissions reductions (tpy) between a control option and the next most effective option.

Note 3. “n/a” indicates that the next most effective control option is “inferior” (i.e., higher cost for less control)

Table ES-4. NO_x Emissions Control System Cost Effectiveness (\$2018)

NO _x Control Option	Total Annualized Cost \$/yr	Expected Emission Reduction tons NO _x /yr	Average Annual Cost Effectiveness (Note 1) \$/ton NO _x removed	Incremental Annual Cost Effectiveness (Note 2) \$/ton NO _x removed
Baseline (Existing SOFA)	---	---	---	---
Combustion Optimization	\$0	589	\$0	\$0
SNCR + Combustion Optimization	\$4,754,000	2,847	\$1,670	\$2,105
SNCR + RRI + Combustion Optimization	\$8,617,000	4,137	\$2,083	\$2,994
SCR – Tail-End Configuration	\$41,268,000	5,912	\$6,981	\$18,402

Note 1. Average cost effectiveness for each control option is the total annual cost divided by the expected emission reduction.

Note 2. Incremental cost effectiveness represents the incremental increase in annual costs (\$/yr) divided by the incremental increase in annual emissions reductions (tpy) between a control option and the next most effective option.

Time Necessary for Compliance (Statutory Factor Two)

Table ES-5 and Table ES-6 provide estimated timeframes needed to implement each of the technically feasible control option. Notably, the estimated timeframes do not account for time needed for North Dakota to develop and implement the regulations; nor the amount of time needed for EPA to take proposed and final action to approve North Dakota's SIP.

Table ES-5. SO₂ Emissions Control System Implementation Schedule

SO ₂ Control Option	Design / Specification / Procurement (months)	Detail Design / Fabrication (months)	Construction / Commissioning / Startup (months)	Total (months after SIP approval)
DSI + Existing FGD	6	6	6	18
FGD Operational Improvements – Increase Ca:S Stoichiometric Ratio	0	0	0	0
DSI + FGD Operational Improvements	6	6	6	18
FGD Upgrades - Replacing Existing Absorbers with New Absorber	8	12	12	32
Dry FGD (CDS) + Existing FF	12	20	18	50
Wet FGD	12	22	22	56

Table ES-6. NO_x Emissions Control System Implementation Schedule

NO _x Control Option	Design / Specification / Procurement (months)	Detail Design / Fabrication (months)	Construction / Commissioning / Startup (months)	Total (months after SIP approval)
Combustion Optimization	0	0	0	0

Energy and Non-Air Quality Environmental Impacts (Statutory Factor Three)

An evaluation of energy impacts indicates that certain control options (e.g., new FGD systems, TE-SCR) will increase auxiliary power requirements due to increased pressure drop, which would adversely impact net plant heat rate. Consequently, heat input to the boiler would need to increase to compensate for the increased auxiliary power requirements while achieving the same net plant output, or net output from the unit would decrease. Collateral environmental impacts include an increase in the solid waste generation with DSI. A summary of the environmental and energy impact analysis is provided in Table ES-7.

Table ES-7. Summary of Energy and Non-Air Quality Environmental Impacts

Control Option	Collateral Environmental & Energy Impacts
<u>SO₂ Control Options</u>	
Replace existing DFGD with New WFGD control system	<ul style="list-style-type: none"> ➤ Increased water consumption ➤ Wet by-product that requires dewatering prior to disposal ➤ FGD wastewater treatment & discharge ➤ Increased auxiliary power requirements and heat rate penalty
Replace existing DFGD with New CDS/FF Control System	<ul style="list-style-type: none"> ➤ Increased auxiliary power requirements and heat rate penalty ➤ Increased solid FGD by-product management and disposal
Replace existing dry scrubber modules with New DFGD modules while keeping existing FF	<ul style="list-style-type: none"> ➤ Requires extended (approximately 12-month) outage of Coyote Unit 1 to demolish and replace the existing scrubber modules
Dry Sorbent Injection	<ul style="list-style-type: none"> ➤ Increased solid FGD by-product management and disposal ➤ Increased auxiliary power requirements and heat rate penalty
<u>NO_x Control Options</u>	
Selective Catalytic Reduction (SCR) - Tail End Configuration	<ul style="list-style-type: none"> ➤ Increased auxiliary power requirements and heat rate penalty ➤ Increased ammonia slip emissions ➤ Potential increase in SO₃ emissions

Remaining Useful Life (Statutory Factor Four)

The Coyote Station owners have not identified dates for the remaining useful life of the unit before the end of what would otherwise be the useful life of the control measures that were evaluated for Coyote Unit 1. Thus, the 20-year equipment life of the control measures was used in the four factor analysis to calculate emission reductions, amortized costs, and cost-effectiveness.

1. INTRODUCTION

Sargent & Lundy, L.L.C. (S&L) was retained by Otter Tail Power Company (Otter Tail) to prepare a Reasonable Progress four-factor analysis for the control of sulfur dioxide (SO₂) and nitrogen oxide (NO_x) emissions from Coyote Station Unit 1 (Coyote Unit 1).³ The evaluation is in response to North Dakota Department of Health's (NDDH) request that Otter Tail prepare a four factor analysis for Coyote Unit 1.

The evaluation includes an assessment of potentially available emission reduction measures for the four statutory factors listed in 40 CFR 51.308(f)(2), and takes into consideration U.S. Environmental Protection Agency's (EPA's) *Draft Guidance on Progress Tracking Metrics, Long Term Strategies, Reasonable Progress Goals and Other Requirements for Regional Haze State Implementation Plans for the Second Implementation Period* (the "Draft EPA Guidance").⁴ Technically feasible SO₂ and NO_x emission reduction measures are evaluated for the following four statutory factors:

- Factor 1: The cost of compliance
- Factor 2: The time necessary to achieve compliances
- Factor 3: The energy and non-air quality environmental impact of compliance
- Factor 4: The remaining useful life of any existing source subject to such requirements

The Reasonable Progress four factor analysis for Coyote Unit 1 (the "Four Factor Analysis") is presented in the following sections:

- Section 2: Facility Description** contains information describing the facility, site location, and existing equipment.
- Section 3: Four-Factor Analysis Requirements** provides a brief description of the Regional Haze Program requirements set forth in 40 CFR 51.308.
- Section 4: Baseline SO₂ and NO_x Emissions** establishes representative baseline SO₂ and NO_x emissions for the period 2013 to present.

³ Coyote Station is co-owned by Otter Tail Power Company (35%), Northern Municipal Power Agency (30%), Montana-Dakota Utilities Co. (25%), and NorthWestern Energy (10%).

⁴ On September 11, 2018, EPA released a "*Regional Haze Reform Roadmap*" announcing its plan to "release a series of implementation tools and guidance documents that will help focus states' efforts and reduce and streamline the time and resources needed to meet the statutory and regulatory requirements for reducing regional haze in National Parks, wildlife refuges, and wilderness areas." EPA stated that it plans to issue a new guidance document on Regional Haze SIP Development by Spring, 2019. Otter Tail Power reserves the right to update and modify this four-factor analysis, as needed, to be consistent with any new guidance issued by the agency.

- Section 5: SO₂ and NO_x Control Measures** identifies potentially available emission control technologies, and evaluates each control option for technical feasibility and effectiveness.
- Section 6: Costs of Compliance (Statutory Factor One)** evaluates the cost and cost-effectiveness of each technically feasible control option.
- Section 7: Time Necessary for Compliance (Statutory Factor Two)** provides typical timelines required to design, engineer, procure and install the technically feasible control options.
- Section 8: Energy and Non-Air Quality Environmental Impacts (Statutory Factor Three)** identifies the energy and non-air quality environmental impacts associated with each technically feasible control option.
- Section 9: Remaining Useful Life (Statutory Factor Four)** includes a discussion of the planned remaining useful life of Coyote Unit 1.
- Section 10: Summary and Conclusions**

Appendix B: SO₂ Control Cost Effectiveness Estimates

Appendix C: NO_x Control Cost Effectiveness Estimates

2. FACILITY DESCRIPTION

Coyote Station, located near Beulah, ND, commenced commercial operation in 1981. The facility is a single unit station with one 451 MWg (approximate) Babcock and Wilcox cyclone boiler (Coyote Unit 1). Coyote Unit 1 is designed to fire North Dakota lignite, and is equipped with separated overfire air (SOFA) for NO_x control, and dry flue gas desulfurization (DFGD or dry FGD) and fabric filter baghouse (FF) for SO₂ and particulate matter (PM) control. Lignite is delivered to the Station from the Coyote Creek Mine, whose primary operations are approximately 3-4 miles from the Coyote Station.

Table 2-1 provides a summary of the process parameters used for the Coyote Unit 1 Four Factor Analysis. Process parameters listed in Table 2-1 were developed from information provided by OTP.⁵

Table 2-1. Process Parameters

Process Parameter	Coyote Unit 1
Boiler Type	Cyclone
Boiler Manufacturer	B&W
Full Load (MWg)	451
Full Load Boiler Heat Input (MMBtu/hr)	4,900
Full Load Coal Flow (lb/hr)	700,700
Boiler Excess Air (%)	14.0
Air Heater Leakage (%)	22.0
Bottom Ash/Fly Ash Ratio	65/35
Flue Gas Conditions at Air Heater Outlet	
Temperature (F)	330
Mass Flow Rate (lb/hr)	6,532,000
Volumetric Flow rate (acfm)	2,485,000
Annual Average Fuel Sulfur Content (%)	0.82 - 1.06
Annual Average Uncontrolled SO ₂ Emissions (lb/MMBtu)	2.42 - 3.12

⁵ These process parameters are representative of typical average conditions. They should not be construed as maximum values or unit design values.

3. FOUR-FACTOR ANALYSIS REQUIREMENTS

3.1 REGIONAL HAZE RULE BACKGROUND

Section 169A of the 1977 Amendments to the Clean Air Act (CAA) sets forth a program for protecting visibility in Federal Class I areas which calls for the “prevention of any future, and the remedying of any existing, impairment of visibility in mandatory Federal Class I areas which impairment results from manmade air pollution.” Federal Class I areas include national parks, memorial parks, and wilderness areas over a certain size. Figure 3-1 shows the locations of the 156 federally mandated Class I areas. Federal Class I areas located within North Dakota include the Theodore Roosevelt National Park and the Lostwood National Wildlife Refuge.

Figure 3-1. Federal Class I Areas

On July 1, 1999, the U.S. Environmental Protection Agency (EPA) published regulations implementing Section 169A of the CAA, establishing a comprehensive visibility protection program for Federal Class I areas (the Regional Haze Rule).⁶ The Regional Haze Rule requires each state to develop, and submit for approval by EPA, a

⁶ 64 FR 35713

state implementation plan (SIP) detailing the state's plan to protect visibility in Class I areas. In 2017, EPA issued a final rule revising portions of the 1999 Regional Haze Rule.⁷ The 2017 Rule requires states to determine the baseline (2000 - 2004) visibility condition for the 20 percent most impaired days and requires that the long-term strategy and reasonable progress goals (RPGs) must provide for improvement in visibility for the most impaired days, relative to the baseline period. Specifically, states must determine the rate of improvement in visibility that would need to be maintained during each implementation period in order to reach natural conditions by 2064 for the 20 percent most impaired days, given the starting point of the baseline visibility condition.

To address the combined visibility effects of various pollution sources over a wide geographic region, EPA designated five Regional Planning Organizations (RPOs) to assist with the coordination and cooperation needed to address the visibility issue. The five RPOs are shown in Figure 3-2. North Dakota is a member of the Western Regional Air Partnership (WRAP), which serves as the RPO for visibility protection at 118 Class I areas in the 15 western states.

Figure 3-2. Regional Planning Organization Map

⁷ Final Rule: Protection of Visibility: Amendments to Requirements for State Plans, 82 FR 3078, January 10, 2017

3.1.1 First Implementation Period

The Regional Haze Rule established a schedule setting forth deadlines by which the States must submit their initial regional haze SIPs and subsequent revisions to the SIPs. Regional Haze SIPs for the initial planning period were due in 2007, with subsequent SIP updates due in 2018 and every 10 years thereafter.⁸

Regional Haze SIP requirements for the first planning period required that states incorporate into their plans the core program requirements in 40 CFR 51.308(d), including: (1) establishing reasonable progress goals (RPGs) for each Class I area within the state that provide for measurable progress towards achieving natural visibility conditions; (2) developing a long-term strategy (LTS) including enforceable emissions limitations and compliance schedules to achieve the RPGs; and (3) developing plans to monitor and assess the effectiveness of the LTS to achieve the RPGs over the prior implementation period and affirmation of or revision to the RPGs.

The Regional Haze Rule requires that states determine the consistent rate of progress over time needed to attain natural visibility conditions on the 20 percent most anthropogenically impaired days by the year 2064. This “glidepath” is referred to as the uniform rate of progress (URP) line. States must consider the URP, and the emission reduction measures needed to achieve this level of improvement, when developing their RPGs and LTS. Regulations at 40 CFR 51.308(g) require each state to submit progress reports, in the form of SIP revisions, every 5 years following the submission of the initial SIP. These progress reports must evaluate the progress made towards the RPGs for Class I areas located within the state as well as those Class I areas located outside the state that may be affected by emissions from within the state.

3.1.1.1 Best Available Retrofit Technology

As a one-time requirement during the first implementation period, potential best available retrofit technology (BART) controls had to be evaluated for certain large stationary sources. States were required to conduct BART determinations for “BART-eligible” sources anticipated to cause or contribute to any visibility impairment in one or more Class I area. BART-eligible sources included coal-fired electric generating units (EGUs) that were in existence on August 7, 1977, but not in operation prior to August 7, 1962. In its determination of BART, states were required to take into consideration the costs of compliance, the energy and nonair quality environmental impacts of compliance, any existing pollution control technology in use at the source, the remaining useful life of

⁸ On January 10, 2017, EPA made a one-time adjustment to the due date for the second implementation period SIPs (2018 – 2028) by extending the deadline from July 31, 2018 to July 31, 2021 (82 FR 3078).

the source, and the degree of improvement in visibility which may reasonably be anticipated to result from the use of such technology.⁹ As an alternative to requiring source-specific BART controls, states also had the flexibility to adopt an emissions trading program or other alternative program as long as the alternative provided greater reasonable progress towards improving visibility than BART.

3.1.1.2 Reasonable Progress Control Requirements for Coyote Station during First Planning Period

Coyote Unit 1 commenced operation in 1981, and was not classified as a BART-eligible source or subject to the BART requirements. Nevertheless, during the initial planning period, the North Dakota Department of Health (NDDH) evaluated emissions from the Coyote Station as a reasonable progress source. The reasonable progress analysis prepared by NDDH concluded that no additional controls would be required on Coyote Unit 1 during the initial planning period; however, NDDH and Otter Tail reached an agreement whereby Otter Tail committed to install SOFA equipment to reduce NO_x emissions. In the initial planning period SIP NDDH noted that additional SO₂ and NO_x controls for Coyote Unit 1 would be reevaluated during future planning periods to determine if additional emissions reductions would be required.

3.1.2 Second Implementation Period

Second planning period Regional Haze SIPs must be submitted to EPA for review by July 31, 2021. Among other requirements, second planning period SIPs are required to include an assessment of the state's RPGs and LTS. To support states in their efforts to develop the second planning period SIPs, in July 2016 EPA released a draft guidance document titled "*Draft Guidance on Progress Tracking Metrics, Long-term Strategies, Reasonable Progress Goals and Other Requirements for Regional Haze State Implementation Plans for the Second Implementation Period*" ("Draft EPA Guidance").¹⁰ The Draft EPA Guidance document describes key steps states should implement when developing their RPGs and LTS for the second implementation period. Key steps identified in the Draft EPA Guidance are listed in Table 3-1.

⁹ CAA Section 169A(g)(2).

¹⁰ See, EPA-457/P-16-001. On September 11, 2018, EPA released a "*Regional Haze Reform Roadmap*" announcing its plan to "release a series of implementation tools and guidance documents that will help focus states' efforts and reduce and streamline the time and resources needed to meet the statutory and regulatory requirements for reducing regional haze in National Parks, wildlife refuges, and wilderness areas." EPA stated that it plans to issue a new guidance document on Regional Haze SIP Development by Spring, 2019. Otter Tail Power reserves the right to update and modify this four-factor analysis, as needed, to be consistent with any new guidance issued by the agency.

Table 3-1. Key Steps in Developing Regional Haze SIPs for Second Planning Period

1. *Ambient data analysis* – Quantify baseline, current and natural conditions and the uniform rate of progress that would achieve natures conditions in 2064 (40 CFR 51.308(f)(1))
2. *Screening of sources* – Identify the pollutants and emission sources for which a full reasonable progress analysis will be completed and explain why it is appropriate to limit the full analysis to only these sources (40 CFR 51.308(f)(2))
3. *Source and emission control measure analysis* – Identify potential emission control measures for sources selected in the screening step and develop data on the four statutory factors and visibility benefits if they will be considered (40 CFR 51.308(f)(2))
4. *Decisions on the content of the LTS* – Consider applicable factors and decide on new emission controls for incorporation into the LTS (40 CFR 51.308(f)(2))
5. *Regional scale modeling* – Model the emissions reductions that will result from implementation of the LTS and other enforceable measures that will reduce visibility impairment to set the RPGs for 2028 (40 CFR 51.308(f)(3))
6. *Progress, degradation and glidepath checks* – Demonstrate that there will be an improvement on the 20 percent most impaired days. Demonstrate that there is no degradation on the 20 percent clearest days. Compare the 2028 RPG for the 20 percent most impaired days to the 2028 point on the URP line (the glidepath) and, if required, provide additional justification for the reasonableness of the RPG. Revise the LTS if additional measures are identified as necessary to make reasonable progress. (40 CFR 51.308(f)(3))
7. *Additional requirements for SIPs* – Provide additional information necessary to ensure that other requirements of the Regional Haze rule are met.

The Draft EPA Guidance recommends that states evaluate all technically feasible emission control options for stationary sources and source categories identified as having the greatest potential to impact visibility at one or more Class I area. The Draft EPA Guidance recommends several options for states to consider when evaluating potential emission reductions, including work practices, replacement and retrofit controls, existing control upgrades, fuel switching year-round operation of controls, and operating restrictions.¹¹

Emission control evaluations must consider the four statutory factors identified in 40 CFR 51.308(f)(2)(i) (discussed in Section 3.2). In addition, the Draft EPA Guidance notes that control technology assessment recommendations presented in the BART Guidelines continue to be relevant as recommendations for how a state

¹¹ See, Draft EPA Guidance, pgs. 85-86.

should evaluate and select emission control measures for stationary sources.¹² Recommendations in the BART Guidelines that continue to be relevant to the Regional Progress Four Factor Analysis are listed in Appendix D of the Draft EPA Guidance, and include, in general, the recommended approach for evaluating the technical feasibility, effectiveness, costs, and cost-effectiveness of available emission control measures.¹³

3.2 DESCRIPTIONS OF THE FOUR STATUTORY FACTORS

Under 40 CFR 51.308(f)(2)(i), states must consider four statutory factors when evaluating and determining emissions reduction measures from stationary sources, or groups of sources, that are necessary to make reasonable progress towards achieving natural visibility conditions. The four statutory factors are:

5. The costs of compliance;
6. The time necessary for compliance;
7. The energy and non-air quality environmental impacts of compliance; and
8. The remaining useful life of any potentially affected anthropogenic source of visibility impairment.

A brief description of each of the four statutory factors, and EPA's recommendations for evaluating each of the four factors (from the Draft EPA Guidance) is provided below.

3.2.1 Costs of Compliance

Cost estimates should be developed for each technically feasible control option. Costs include the total capital costs to engineer, design, procure, and install the control technology, and annual operating and maintenance (O&M) costs. O&M costs include both fixed and variable O&M. Fixed O&M includes costs that are independent of control system operation and would be incurred even if the control system were shut down. Fixed O&M includes categories such as operating and maintenance labor, administrative charges, property taxes, and insurance. Variable O&M includes the cost of consumables, including reagent (e.g., lime or limestone, ammonia, urea, etc.), by-product management, water consumption, and auxiliary power requirements associated with operating the control system. For existing facilities, O&M cost estimates should represent the control option's incremental increase over current O&M costs.

¹² Draft EPA Guidance, pg. 85. The BART Guidelines are published at 40 CFR Part 51 Appendix Y.

¹³ Draft EPA Guidance, Appendix D, pgs. 186-196.

Capital costs include all costs required to engineer, design, procure, and install equipment needed for the control system. The Draft EPA Guideline recommends that states adhere to the accounting principles described in Chapter 2 Section 1 of EPA's Air Pollution Control Cost Manual (the "Control Cost Manual") when calculating control system costs for a four factor analysis.¹⁴

Section 2.3 of the Control Cost Manual (Section 1, Chapter 2) describes the cost categories generally used to calculate the total capital cost of a retrofit control technology. Cost categories include total capital investment (TCI), which is defined to "include all costs required to purchase equipment needed for the control systems (purchased equipment costs), the costs of labor and materials for installing that equipment (direct installation costs), costs for site preparation and buildings, and certain other costs (indirect installation costs). TCI also includes costs for land, working capital, and off-site facilities." Direct installation costs include costs for foundations and supports, erecting and handling the equipment, electrical work, piping, insulation, and painting. Indirect installation costs include costs such as engineering costs; construction and field expenses (i.e., cost for construction supervisory personnel, office personnel, rental of temporary offices, etc.); contractor fees (for construction and engineering firms involved in the project); start-up and performance test costs (to get the control system running and to verify that it meets performance guarantees); and contingencies.¹⁵

The total annual cost (TAC) of a control option includes the annualized capital recovery cost plus the total annual O&M costs. The Control Cost Manual recommends using an equivalent uniform annual cash flow method to annualize the total capital investment by multiplying the total capital investment by a capital recovery factor (CRF).¹⁶ The product of the total capital investment and CRF gives a uniform end-of-year payment necessary to repay the initial capital investment in "n" years at an interest rate of "i". The CRF is calculated using the following equation:

$$CRF = \frac{i * (1 + i)^n}{(1 + i)^n - 1}$$

Where:

i = interest rate; and

n = economic life of the emission control system

The Draft EPA Guidance suggests that states may use generic cost estimates or estimating algorithms for estimating

¹⁴ Draft EPA Guidance, pg.89.

¹⁵ EPA Air Pollution Control Cost Manual, Sixth Edition, EPA/452/B-02-001, January 2002, pg. 2-5.

¹⁶ Id., at pg 2-21.

control system costs; however, source specific estimates prepared by knowledgeable engineering professionals provide more reliable information than generic cost estimates.¹⁷ Source-specific cost estimate should be well documented for purposes of public comment and EPA review.¹⁸

The total annual cost of each control option (\$/yr) is divided by the total annual emissions reduction (tpy) to determine the control option's average cost-effectiveness on a \$/ton basis. Emissions reductions are calculated based on the difference between baseline annual emissions and post-control annual emissions. The Draft EPA Guidance generally recommends calculating baseline emissions based on projected 2028 emissions assuming source compliance with emission limits that have been adopted and are enforceable. As an alternative, baseline emissions may be based on representative past actual emissions, assuming there is no evident basis for using a different emissions rate.

3.2.2 Time Necessary for Compliance

For stationary sources, the provisions of the BART Guidelines regarding the time necessary for compliance are relevant to reasonable progress analyses. EPA recommends that prior experiences with the planning and installation of new emission controls is the best guide to how much time a particular source will reasonably need for compliance. However, source-specific factors should be considered when evaluating the time necessary to engineer, procure, and install an available and technically feasible control option. Source-specific factors that affect the time necessary to install new emission controls should be identified and documented in the four factor analysis.

3.2.3 Energy and Non-Air Quality Environmental Impacts

For stationary sources, the provisions of the BART Guidelines regarding energy impacts are relevant to reasonable progress analyses. Energy impacts of an emission control measure are a matter of engineering design and control system operation; thus, EPA recommends that prior experience at similar sources will be informative. Energy impacts may be considered in terms of kilowatt-hours or fuels used to operate the control system. The energy impact analysis should focus on direct energy consumption at the source rather than indirect energy inputs needed to produce raw materials for the construction and operation of control equipment.

¹⁷ Draft EPA Guidance, pg. 91.

¹⁸ Id.

For stationary sources, the provisions of the BART Guidelines regarding non-air quality environmental impacts are relevant to reasonable progress analyses. Non-air quality impacts include solid or hazardous waste generation, increased water consumption, wastewater discharge, land use impacts, and impacts to threatened and endangered species or their natural habitat. Characterizing the non-air quality environmental impacts should be done on a source-specific basis. Other guidance intended for use in assessments under the National Environmental Policy Act may be relevant to this evaluation.

Even though states are not required to consider GHG emission impacts, the Draft EPA Guidance encourages states to consider GHG impacts when developing their Long-Term Strategy.¹⁹ As an example, some measures that would reduce emissions that contribute to visibility impairment will also reduce GHG emissions, such as measures that reduce the use of energy produced from combusting fossil fuels with relatively high GHG emissions. Conversely, control measures that require significant energy to capture visibility impairing emissions could result in increased GHG emission. Where a measure necessary to make reasonable progress towards natural visibility conditions would increase GHG emissions, Draft EPA Guidance encourages states to work to harmonize visibility and climate change objectives.²⁰

3.2.4 Remaining Useful Life

For stationary sources, the provisions of the BART Guidelines regarding remaining useful life are relevant to reasonable progress analyses. In general, the remaining useful life of the source itself will be longer than the useful life of the emission control measure under consideration unless there is an enforceable requirement for the source to cease operation sooner. Thus, the useful life of the control measure will normally be used in the four factor analysis to calculate emission reductions, amortized costs, and cost-effectiveness. However, if there is an enforceable requirement for the source to cease operation by a date before the end of what would otherwise be the useful life of the control measure under consideration, then the enforceable shutdown date should be used to calculate remaining useful life and evaluate control technology cost-effectiveness.

¹⁹ Draft EPA Guidance, pg. 92.

²⁰ Id.

3.2.5 Four Factor Analysis Approach

S&L used the following approach to identify SO₂ and NO_x emission control options available to Coyote Unit 1 for inclusion in the Four Factor Analysis:

1. Establish representative baseline emissions achieved with existing controls.
2. Identify all potentially available control options.
3. Evaluate control options for technical feasibility (i.e., availability and applicability).
4. Eliminate control options that are not technically feasible or would have no practical application on Coyote Unit 1.
5. Determine the control effectiveness of each technically feasible control option.
6. Evaluate each technically feasible control option for the four statutory factors.

4. BASELINE SO₂ AND NO_x EMISSIONS

The first step in developing the Four Factor Analysis is to establish Coyote Unit 1 baseline SO₂ and NO_x emissions. To establish representative baseline emissions, S&L evaluated Coyote Unit 1 operating data for the period January 1, 2013 to June 30, 2018 to identify periods of normal operation (i.e., periods of operation when the boiler was not limited by infrequent or extraordinary operating restrictions). Based on review of fuels consumed, heat input to the boiler, boiler heat rates, power generation, and capacity factors, as well as input from OTP, it was determined that the operating periods of January 1, 2013 to December 31, 2014 and January 1, 2016 to June 30, 2018 were representative of normal operation. The year 2015 was not considered to be representative because Coyote Unit 1 was limited to approximately 50% load due to a boiler feed pump (BFP) overspeed event that damaged one of the unit's two 50% BFPs; thus, only one BFP was available throughout most of the year. Therefore, the periods January 1, 2013 to December 31, 2014, and January 1, 2016 to June 30, 2018 are representative of normal operation during the baseline period, and it was determined that SO₂ emissions during that period are also representative. In June 2016, Unit 1 SOFA upgrades were completed for the purpose of reducing NO_x emissions; thus, the representative baseline period for NO_x emissions was determined to be from July 1, 2016 to June 30, 2018.

Baseline annual SO₂ and NO_x emissions were determined based on data obtained from the Coyote Unit 1 continuous emissions monitoring system (CEMS) that was reported to EPA's Clean Air Markets. The annual average emission rate during the representative time period was used to establish baseline annual emissions (in terms of tons per year). Representative baseline emission factors (in terms of pounds per million British Thermal Units (lb/MMBtu)) were developed using baseline annual average emissions and the respective baseline heat inputs. Table 4-1 provides a summary of the Coyote Unit 1 SO₂ and NO_x representative baseline emissions; additional details are included in Appendix A.

Table 4-1. Coyote Unit 1 Baseline Emissions

Pollutant	Baseline Controls	Emissions		Heat Input	Notes
		lb/MMBtu	tons/yr	MMBtu/yr	
SO ₂	DFGD/FF	0.85	12,994	30,562,287	SO ₂ emissions based on annual average tpy for period January 2013-June 2018 (excluding 2015)
NO _x	SOFA	0.46	7,363	32,301,802	NO _x emissions based on annual average tpy for period July 2016 to June 2018 (post-SOFA upgrades)

5. SO₂ AND NO_x CONTROL MEASURES

S&L used a top-down approach to identify and evaluate the technical feasibility and effectiveness of potentially available SO₂ and NO_x control measures. S&L followed Steps 1 thru 3 of the top-down approach described in the BART Guidelines to identify all available retrofit emission control measures, eliminate technically infeasible options, and evaluate the effectiveness of the technically feasible options.²¹ A brief description of each step is provided below.

Step 1 - Identify All Available Control Options

Available control options are those air pollution control technologies with a practical potential for application to the emission unit and the regulated pollutant under evaluation. Air pollution control technologies can include a wide variety of available methods, systems, and techniques for control of the affected pollutant, and include not only existing controls for the source category but also take into account technology transfer of controls that have been applied to similar source categories and gas streams. Technologies which have not been applied to (or permitted for) full scale operations need not be considered as available.²²

In an effort to identify all potentially available emission control technologies, S&L searched a broad range of information sources including, but not necessarily limited to:

- EPA's RACT/BACT/LAER Clearinghouse;
- EPA's New Source Review (NSR) and Clean Air Technology Center (CATC) Web sites;
- BART evaluations prepared during the initial Regional Haze planning period;
- Information from control technology vendors and engineering/environmental consultants;
- Federal and State NSR permits and Best Available Control Technology (BACT) determinations for similar sources; and
- Technical journals, reports, newsletters and air pollution control seminars.

Step 2 - Eliminate Technically Infeasible Control Options

In Step 2, S&L evaluated the technical feasibility of the control options identified in Step 1 with respect to source-specific and unit-specific factors. Control technologies are technically feasible if either: (1) they have been

²¹ See, 40 CFR Part 51 Appendix Y, Section IV.D.

²² Id., at IV.D.1.

installed and operated successfully for the type of source under review under similar conditions; or (2) the technology could be applied to the source under review. In order for a control option to be technically feasible, it must be “available” and “applicable” to the source under consideration. A technology is considered “available” if the source owner may obtain it through commercial channels. An available technology is “applicable” if it can reasonably be installed and operated on the source type under consideration.²³

Control technologies that are technically infeasible (i.e., not available or not applicable to the source under consideration) are eliminated for further evaluation. A demonstration of technical infeasibility must be based on physical, chemical and engineering principals, and must show that technical difficulties would preclude the successful use of the control option on the emission unit under consideration. The economics of an option are not considered in the determination of technical feasibility/infeasibility.

Step 3 - Evaluate Technically Feasible Control Technologies for Effectiveness

Step 3 involves evaluating the control effectiveness of all the technically feasible control alternatives identified in Step 2 for the pollutant and emissions unit under review. Control effectiveness should be expressed using a metric that ensures an “apples-to-apples” comparison of emissions performance levels among options, and is generally expressed as the rate that a pollutant is emitted after installation of the control measure. Control technology evaluations for existing sources should consider ways to improve the performance of existing control devices. Special circumstances pertinent to the specific unit under review should be identified and taken into consideration when assessing the capability of the control alternative and determining control effectiveness.

For this evaluation, S&L assessed the technically feasible SO₂ and NO_x control options for effectiveness on Coyote Unit 1. As discussed above, Coyote Unit 1 is an existing cyclone boiler designed to fire North Dakota lignite. The unit is equipped with SOFA for NO_x control, and dry FGD and FF for SO₂ and PM control.

²³ A more detailed description of control technology “availability” and “applicability” is provided in 40 CFR Part 51 Appendix Y, Section IV.D.2.

5.1 SO₂ EMISSIONS CONTROLS

5.1.1 Identify Available SO₂ Control Options

Based on a review of available SO₂ control technologies, as well as operational practices and equipment upgrades implemented on existing control systems, potentially available options to control SO₂ emissions from Coyote Unit 1 are listed in Table 5-1.

Table 5-1. Available SO₂ Control Options

SO ₂ Control Technologies

5.1.2 Technical Feasibility of Available SO₂ Control Options

Potentially available SO₂ control options identified in Table 5-1 were evaluated for technical feasibility (i.e., availability and applicability to Coyote Unit 1) based on a review of physical, chemical, and engineering principals, and an assessment of commercial availability. Options determined to be technically infeasible, or options that have no practical application to Coyote Unit 1, were eliminated from further review. S&L evaluated the effectiveness of the control options determined to be technically feasible, and established an emissions performance level (i.e., control emissions rate) for each.

5.1.2.1 Fuel Switching

One potential strategy for reducing SO₂ emissions is to reduce the sulfur content of the coal. Limiting the amount of sulfur in the coal directly limits the amount released during the combustion process, and would reduce SO₂ loading to the dry scrubber. Coyote Unit 1 is a cyclone boiler designed to fire North Dakota lignite as the primary fuel. Lignite fired at the Coyote Station is mined and supplied to the station from the nearby Coyote Creek Mine. The mine, which is owned and operated by Coyote Creek Mining Company, has primary mining operations

approximately 3-4 miles southwest of Coyote Station and can be considered a mine mouth plant. Previous regulatory and court decisions have concluded that requiring a mine mouth facility to evaluate low sulfur coal would require the facility to redefine its fundamental purpose and design; therefore, fuel switching can be rejected as an available control option.²⁴ Because the use of North Dakota lignite from the Coyote Creek Mine is an inherent aspect of Coyote operation, fuel switching will not be evaluated.

5.1.2.2 Existing DFGD Operational Improvements and Equipment Upgrades

Operational and other design changes/upgrades to the existing dry scrubber may provide an opportunity for additional SO₂ removal and allow the unit to achieve lower controlled SO₂ emissions. S&L, working with OTP personnel, identified a number of potentially feasible operational changes that may be available to increase SO₂ removal efficiency with the existing equipment. Potentially available operational and design changes to the existing control system are summarized in Table 5-2. A detailed discussion of each of these options is provided in the following sections.

Table 5-2. FGD Operational Improvements and Equipment Upgrades

Adding an Absorber Module
Replacing Existing Absorbers with New Absorber Modules

Lime Quality

The quantity of lime (CaO) available in a dry scrubbing system compared to the amount of SO₂ entering the system is called the stoichiometric ratio (generally referenced as the Ca:S stoichiometric ratio). Reagent quality directly

²⁴ In re: Prairie State Generating Company, PSD Appeal No. 05-05, Slip. Op. at 36 (2006)

affects the Ca:S stoichiometric ratio in DFGD control systems. Using a high quality lime increases the availability of hydrated lime to support process chemistry, and reduces the lime slurry injection rate needed for SO₂ removal.

Lime quality is measured both by the CaO content and reactivity of the lime product. In a dry scrubber, CaO is combined with water to form hydrated lime or calcium hydroxide (Ca(OH)₂), which provides the calcium that is needed to react with SO₂ in the flue gas. With a higher quality lime, more calcium hydroxide is available to react with SO₂. Lime products with a CaO content of 90% or greater are generally considered high quality lime. Lower quality lime products have a lower CaO content and higher quantity of inert material. Reactivity of the lime is measured by the temperature rise when the lime is slaked (i.e., water addition). In general, porous lime products have higher reactivity which is demonstrated by achieving a temperature rise of approximately 40 °C within 3 minutes of adding water.

Based on a review of available lime analyses, and a review of operating data from the existing lime slaking system, Coyote Unit 1 currently procures a high quality lime for use in the dry scrubbers. The typical CaO content of the lime used at Coyote is 90% or greater, and when slaked can achieve a 39.4 °C temperature rise in 3 minutes of adding water. For these reasons, changing the lime quality is not considered a technically feasible operational change available to control SO₂ emissions from Coyote Unit, and will not be evaluated further.

Ca:S Stoichiometric Ratio

Other operational changes that may be available to increase the Ca:S stoichiometry in the existing dry scrubber include: (1) increasing the byproduct recycle rate; and/or (2) increasing the quantity of fresh hydrated lime introduced to the system. Due to the cost savings that may be realized with the first option, some facilities with existing DFGD controls have opted to increase solids recycle rates to as high as 40-50% solids to achieve an incremental increase in SO₂ reduction, if capacity was available in the byproducts handling system. If capacity is not available, increasing fresh lime addition to the system may also be a viable option to increase the Ca:S stoichiometric ratio.

Solids from a dry scrubber consist of fly ash, reaction byproduct, and residual unreacted hydrated lime. On Coyote Unit 1, solids collected in the fabric filter hoppers are conveyed to either a dry storage silo for disposal or to a recycle fly ash silo where it is used as make-up for the reactant slurry. The recycle system is designed to utilize a portion of the unreacted lime rather than disposing of all of the solids. Recycle solids are combined with the fresh lime addition to provide the makeup lime needed for SO₂ reduction. Increasing the recycle rate can increase the

amount of hydrated lime added to the system (i.e., stoichiometric ratio) without increasing the quantity of fresh lime added to the system.

Based on information provided by the station, the DFGD system on Coyote Unit 1 currently operates the recycle system at approximately 24% solids. The Coyote Unit 1 recycle system is operating within the original design conditions and system capacity. The plant has tested higher recycle rates (up to 28-30% solids), but at these higher rates plant personnel reported significant problems with the atomizer wheels spilling over and pluggage of various strainers. Based on the adverse operational impacts observed during these tests, as well as the design limitations of the existing dry scrubber modules, increasing the recycle % solids is not considered a technically feasible SO₂ control option for Coyote Unit 1.

As an alternative to increasing the recycle rate, the Ca:S stoichiometric ratio in the system may be increased by increasing the quantity of fresh lime introduced to the system. Testing was completed in October 2018 on Coyote Unit 1 to determine the impact of increasing the amount of fresh lime slurry fed to the atomizer feed tanks while adjusting the amount of recycle slurry in order to maintain the design 24% solids to the absorber. During the test program Coyote Unit 1 was able to achieve an average controlled SO₂ emission rate of 0.50 lb/MMBtu without significant adverse operational impacts and represents an average emission rate that Coyote would be expected to achieve on an on-going long-term basis under normal operating conditions. The emission rate should not be construed to represent proposed permit limits. Corresponding permit limits must be evaluated on a control system-specific basis; however, an additional 10-15% margin would likely be needed to account for operating margin.

Increasing the quantity of fresh lime introduced to the system will require the existing atomizer wheels to be upgraded from the eight (8) nozzle wheel to a twelve (12) nozzle wheel to mitigate for potential plugging and spill-over issues caused by the percent solid limitation of the existing atomizer wheels (see, Section 5.1.2.2 Atomizer Replacement), and to prevent the possibility of moisture carry-over that could occur with the increase in lime slurry flow. Although upgrades to the existing atomizer wheels and nozzles will be required, increasing the Ca:S stoichiometric ratio by adding additional fresh lime to the system is considered a technically feasible SO₂ control option for Coyote Unit 1, and will be included in the Four Factor Analysis.

Approach to Saturation Temperature

The reaction of SO₂ with Ca(OH)₂ in a dry scrubber is driven by the absorber temperature. Water surrounding the lime slurry droplet allows SO₂ to dissolve into the liquid and facilitates the reaction between lime and SO₂. The

temperature differential between the inlet and the outlet of the DFGD is used as a driving force for SO₂ removal; however, outlet temperatures must be maintained above the saturation temperature to ensure byproducts exiting the absorber module are dry. Residence time within the absorber vessel, drying time, and exit temperature are all important design parameters for a dry scrubbing system.

Inlet temperature to the dry scrubbing module is relatively constant; therefore, temperature differential across the module is a function of the outlet temperature. As a general rule-of-thumb, the closer the outlet temperature is to the adiabatic saturation temperature, the higher the SO₂ removal efficiency.

Operating a dry scrubbing system at outlet temperatures significantly above the adiabatic saturation temperature accelerates water evaporation from the reactant slurry, limits SO₂ absorption into the droplet, and limits the reaction between the lime and SO₂. Reducing the temperature in the absorber closer to the saturation point can provide additional SO₂ removal. On the other hand, the absorber module may not have sufficient residence time to dry all slurry droplets if the system is operated too close to adiabatic saturation, which would result in deposits in the absorber module, corrosion, and severe operational problems. Therefore, maintaining an absorber outlet temperature close to the point of saturation, while staying above it, is vital for optimal reaction kinetics.

The Coyote Unit 1 dry scrubbers currently operate at an outlet temperature of 190-210 °F, which is approximately 55-75 °F above the adiabatic saturation temperature and within original the OEM design steady state operating parameter of 190°F at the stack. More recent dry scrubbing systems have been designed to operate at 30 °F approach to adiabatic saturation. The station has attempted to lower the outlet temperatures to 165-170°F, however, this change caused significant corrosion of the absorber vessels and downstream equipment. Corrosion was likely due to the fact that the Coyote Unit 1 scrubbers were not able to completely dry the slurry droplets because the absorber vessels were designed with a residence time of approximately 1.0 second. More recent dry scrubbers are designed with approximately 10 seconds of residence time.

Figure 5-1 provides a simplified drawing of the Coyote Unit 1 scrubber compared to more recent DFGD designs, and depicts the arrangement limitation causing Coyote's shorter residence time. The low residence time limits the scrubbers ability to dry all slurry droplets when the system is operated too close to the approach to adiabatic saturation temperature. Due to the design limitations of the existing absorber vessels, reducing the outlet temperature is not considered a technically feasible SO₂ control option for Coyote Unit 1, and will not be evaluated further.

Figure 5-1. Comparison of Typical SDA/FF and Coyote Unit 1 SDA/FF Arrangement

Atomizer Replacement

Spray droplet size is an important parameter in the design and operation of a dry scrubber, and can improve lime utilization and SO₂ removal. Finer spray will increase the surface area of the slurry droplets exposed to the flue gas. Greater surface area increases the potential for SO₂ to absorb into the moisture of the slurry droplets. Droplet fineness also plays a role in particle drying time. Larger droplets can have a negative effect on the slurry drying time which can lead to moisture carryover to downstream equipment causing buildup and corrosion.

The Coyote Unit 1 dry scrubber, provided by Combustion Engineering, is designed with three (3) rotary atomizers, each with an eight (8) nozzle wheel in each absorber module to achieve a fine slurry spray. The design of the atomizer and speed at which the wheel rotates are controlling factors for the size and form of the droplets in the spray. The design and speed of atomizers is highly dependent on the spray pattern needed to mix with the hot flue gas in the scrubber module for optimum absorption of SO₂ while also preventing wetting of the absorber walls.

Based on S&L's assessment of the existing control system, previous testing completed by the station, and input from station operators, the existing DFGD system is limited in residence time, and the ability to increase the recycle ratio (solids content) to allow for more effective Ca:S contact in the scrubber vessels. The existing atomizers with eight (8) nozzle wheels would need to be upgraded to a twelve (12) nozzle wheel to mitigate for potential plugging and spill-over issues that could occur with the increased Ca:S stoichiometric ratio (discussed in Section 5.1.2.2). Based on engineering judgment, new 12 nozzle atomizers would improve spray atomization to produce slurry droplets that are smaller in size than the droplets produced by the existing nozzle design. Improved materials of construction would also allow for higher solids content in the slurry without detrimental equipment pluggage or spill-over.

Replacing the existing nozzles with a more recent 12 nozzle wheel design would provide better atomization of the slurry spray and allow for more effective Ca:S contact in the absorber vessels. However, nozzle replacement would not, on its own, be expected to provide a significant increase in SO₂ control. Nozzle upgrades coupled with operational changes designed to increase the Ca:S stoichiometric ratio is a technically feasible option that would be expected to provide additional SO₂ control (See, Section 5.1.2.2 Ca:S Stoichiometric Ratio).

Slaker Replacement

Lime slurry, the reagent used for SO₂ removal in a dry scrubber, is produced by mixing pebble lime with heated water in a slaker; this process is referred to as “slaking”. The slaker is operated at an optimum water-to-lime ratio (typically between 3:1 and 6:1) to produce lime slurry by metering the amount of water and the amount of lime added to the slaker. Slakers are typically designed to produce a lime slurry between 15-20% solids. The lime slurry is added to recycle slurry in a mix tank and then sent to the atomizer where it is sprayed into the scrubber for SO₂ removal.

Coyote Unit 1 still operates the original Dorr-Oliver detention slakers. The slakers operate at a 5:1 water-to-lime ratio and approximately 18% solids, which is in line with the design as well as industry practice. Therefore, replacing the slakers would not result in improved Ca:S contact in the absorber vessels or provide additional SO₂ removal. Replacing the lime slakers is not considered a technically feasible SO₂ control option for Coyote Unit 1, and will not be evaluated further.

Adding an Absorber Module

Another option for extending the residence time within the reactor modules and increasing Ca:S contact would be to add an additional absorber module. The existing system is designed with four absorber modules that share three fabric filter zones. The system is designed to operate with four modules at full load, three or four modules at 75% load and two modules at 50% load. At full load, the flue gas residence time in the reactor modules is approximately 1.0 second. More recent dry scrubbing systems have been designed with reaction vessel residence times of 10 seconds or more.

One potential option available to the Coyote Station to increase absorber module residence time would be to add an additional absorber module to the existing dry scrubbing system. The number of absorber modules used in a DFGD system is dependent on multiple operating parameters, including the flue gas flow rate and SO₂ concentrations. DFGD absorber modules are typically specified with minimum and maximum flue gas flow rates. If the absorber

modules are oversized, flue gas velocities through the module can be too low, causing solids dropout inside the vessel. If the absorber modules are undersized, flue gas velocities can be too high, causing residence time to fall below recommended levels.

Dry scrubbing units that are operating at flue gas volumes significantly above the design flow rate can benefit from adding an extra module to the system. The module would be placed in parallel with the existing modules to achieve a similar pressure drop through each vessel and to ensure equal flue gas distribution to the vessels. Although adding an absorber module would likely allow additional residence time for the SO₂ removal reactions to occur, it would require extensive engineering and modifications to the existing system. More importantly, the Coyote Unit 1 absorber module design is no longer available from Combustion Engineering, and it would likely not be possible to procure a commercial offering from another technology vendor that would be compatible with the existing modules. Therefore, incorporating an additional absorber module into the existing system is not a commercially available or technically feasible SO₂ control strategy for Coyote, and will not be evaluated further.

Replacing Existing Absorbers with New Absorber Modules

Replacing the existing modules with new absorber modules would require significant engineering and facility modifications. Based on a preliminary review of the control system layout, the only practical location for this option would be to construct the new vessels in the same location as the existing modules. Locating the new modules adjacent to the existing absorber modules would require flue gas to be redirected from the air heater outlets to the new absorbers and back to the existing fabric filters, which would likely result in significant solids dropout and other operational issues. Therefore, locating the new absorber modules adjacent to the existing absorber modules is not considered a technically feasible option.

Installing the new absorber vessels in the same location as the existing dry scrubber modules would require Coyote Unit 1 to be taken off-line for an extended period of time. OTP could not operate the unit while the existing modules were dismantled and removed, or while the new absorber modules, duct work, and other system tie-ins were installed. Based on construction schedules for new DFGD systems, and taking into consideration decommissioning of the existing dry scrubber modules, this option would likely require an outage of at least 12-months and would require Coyote to purchase replacement power during this period. In comparison, a typical major outage at Coyote Station is only 6-8 weeks. Outage costs would add significantly to the cost of this control option.

Although replacing the existing dry scrubber modules with new DFGD reactor vessels would require a long outage, there is no technical basis for eliminating this option from the analysis. Replacing the exiting dry scrubber modules with new absorber modules would address the design and operational limits of the existing system. The new absorber modules could be designed to provide additional Ca:S contact and residence time between the exhaust gas and the slurry, and would likely allow OTP to reduce the approach to saturation temperature, design parameters which would increase overall SO₂ removal.

Coyote Unit 1 consistently achieves overall removal efficiencies in the range of approximately 65-73% with the existing dry scrubbing system. Based on engineering judgment and industry practice, it is expected that the fabric filter provides approximately 10-15% of the overall removal in the DFGD system. Assuming 10-15% removal in the fabric filter, approximately 60% of the SO₂ removal is achieved in the existing absorber modules based on the current coal sulfur content. Estimated SO₂ removal efficiencies across the existing DFGD system are shown in Table 5-3.

Table 5-3. Existing SO₂ Removal Efficiencies

Existing Scrubber Modules	Existing Fabric Filter	Overall
Inlet: 2.83 lb/MMBtu Outlet: 1.14 lb/MMBtu Efficiency: 60% of uncontrolled Contribution: 85% of overall removal	Inlet: 1.14lb/MMBtu Outlet: 0.85 lb/MMBtu Efficiency: 11% of uncontrolled Contribution: 15% of overall removal	Inlet: 2.83 lb/MMBtu Outlet: 0.85 lb/MMBtu Efficiency: 70%

Based on SO₂ removal efficiencies achieved in practice on existing units equipped with DFGD, it is anticipated that replacing the existing absorber modules with new scrubber modules could increase removal across the scrubber to approximately 80%, and increase overall removal efficiencies to approximately 91%. It should be noted that Coyote is expected to receive higher sulfur content coal in the future; therefore, the new scrubber vessel SO₂ removal analysis is based on this higher sulfur content coal. The removal efficiencies for this option are shown in Table 5-4.

Table 5-4. New Scrubber Vessel SO₂ Removal Efficiencies

New Scrubber Modules	Existing Fabric Filter	Overall
Inlet: 3.12 lb/MMBtu ^(Note 1) Outlet: 0.62 lb/MMBtu Efficiency: 80% of uncontrolled Contribution: 88% of overall removal	Inlet: 0.62 lb/MMBtu Outlet: 0.29 lb/MMBtu Efficiency: 11% of uncontrolled Contribution: 12% of overall removal	Inlet: 3.12 lb/MMBtu Outlet: 0.29 lb/MMBtu ^(Note 2) Efficiency: 91%

Note 1. Inlet SO₂ rate based on anticipated future fuel sulfur content.

Note 2. Emission rates shown represent average emission rates that the control options would be expected to achieve on an on-going long-term basis under normal operating conditions for Coyote Unit 1. Emission rates are provided for comparative purposes, and should not be construed to represent proposed permit limits. Corresponding permit limits must be evaluated on a control system-specific basis; however, an additional 10-15% margin would likely be needed to account for operating margin.

Replacing the existing dry scrubber modules with new absorber modules is a technically feasible control technology option that would provide an incremental increase in overall SO₂ removal efficiency. However, this option would require Coyote Unit 1 to be taken off-line for an extended period of time (approximately 12 months). Outage costs associated with the extended outage are included in the four-factor cost impact evaluation for this option. Given the constructability issues and extended outage requirements associated with replacing the existing dry scrubber modules, this may not be a practical option for Coyote; nevertheless, it will be included as a technically feasible SO₂ control option in the Four Factor Analysis.

5.1.2.3 Existing FGD + Dry Sorbent Injection

Alkali based sorbent injection is a proven technology for the removal of sulfur trioxide (SO₃) and other acid gases from coal-fired power plant flue gas, and can be used to provide SO₂ control. Sorbent is injected into the ductwork after the furnace and prior to the particulate collection device, where it reacts with SO₂ and other acid gases. Sorbent injection systems are relatively simple systems consisting of material storage, feeding mechanism, blower or transfer line, and an injection device. For SO₂ control on Coyote Unit 1, sorbent would be injected upstream of the dry scrubber to provide an incremental reduction in the concentration of SO₂ in the flue gas at the inlet to the dry scrubber.

Sorbents react with SO₂, and other acid gases, in the flue gas when injected at an appropriate rate and within the proper temperature range for that sorbent. The resulting particulate matter is removed from the flue gas by the particulate control system. The process works through neutralization of the acid gases with the alkaline sorbent. The neutralization reaction occurs as long as the sorbent remains in contact with the gas in the flue gas duct work within the required temperature range.

Dry sorbents that have been used for SO₂ control on coal-fired boilers include:

- Hydrated Lime (Ca(OH)₂)
- Trona or Sodium Bicarbonate (SBC)

The following wet sorbents have also been used for acid gas control at coal-fired power generating stations:

- Sodium Bisulfite (SBS)
- Soda Ash

Dry sorbents, including hydrated lime, Trona, and SBC would be injected pneumatically as a dry powder into the flue gas ductwork upstream of the Coyote Unit 1 dry scrubber. Trona and SBC are both sodium-based sorbents, which react with SO₂ to form sodium salts. Hydrated lime would react with SO₂ to form calcium sulfate salts. The hydrated lime reactions are the same reactions that are taking place in the existing dry scrubber.

Hydrated lime is less reactive than the sodium based dry sorbents; thus, higher injection rates and longer residence time would be required to achieve the same removal efficiency. However, hydrated lime has a lower unit cost compared to other sorbent options, offsetting the higher injection rates. It is also important to note that the hydrated lime chemistry involves the same reactions, and forms the same calcium salts, as those currently taking place in the dry scrubber reaction vessels. Therefore, using hydrated lime as the sorbent would not introduce any new constituents into the dry scrubbing system, and could potentially increase the Ca:S stoichiometry in the dry scrubber.

Because of the higher reactivity of sodium based sorbents, less reactant may be required to achieve the same removal efficiency; however, injecting a sodium-based sorbent into the flue gas upstream of the Coyote Unit 1 dry scrubber would introduce new chemical constituents into the scrubber and into the fly ash/scrubber byproduct material. This could prove problematic as sodium compounds are water soluble, and introducing sodium into the system could adversely affect the characteristics of the byproduct solids generated by the system. Detailed studies and demonstration tests would be needed to ensure that introducing relatively large amounts of sodium would not adversely affect scrubber operation or result in solids disposal issues.

SBS and soda ash (Na₂CO₃) injection are wet injection technologies typically used for SO₃ mitigation. SBS and soda ash can be injected into the flue gas upstream or downstream of the air heater as a 10% solution (by weight) using dual fluid atomizers. Both products will react with SO₂ and SO₃ to form sodium salts, which can be collected in the downstream particulate collection device. URS/Codan Associates own the patent for this SBS control process. Based on conversations with URS, their SBS technology is generally more economical using soda ash,

and all recent projects have used soda ash. However, as with the dry sodium-based injection systems, these systems would introduce sodium into the Coyote Unit 1 DFGD control system.

Sorbent injection (dry or wet) upstream of the existing dry scrubber is a technically feasible and commercially available SO₂ control option for Coyote Unit 1. Taking into consideration the fact that Coyote is currently equipped with a calcium-based dry scrubbing system, hydrated lime dry sorbent injection would be the most practical, and potentially the most effective, sorbent injection control option. Sodium-based systems would require extensive testing to determine the potential impacts associated with introducing significant quantities of sodium into the existing system, and are not considered practical control options for Coyote Unit 1.

Based on engineering judgment, and assuming adequate residence time in the duct work upstream of the existing dry scrubber, hydrated lime injection could reduce SO₂ concentrations at the dry scrubber inlet by approximately 35%. Based on future design fuel characteristics, this would reduce SO₂ concentrations at the dry scrubber inlet from approximately 3.12 lb/MMBtu to approximately 2.03 lb/MMBtu. Applying the current scrubber SO₂ removal efficiency of 71% (dry scrubber plus fabric filter), would result in a controlled SO₂ emission rate of 0.58 lb/MMBtu. DSI upstream of the existing dry scrubbing system is considered a technically feasible SO₂ control technology; however, flow modeling and field testing at Coyote Unit 1 would be needed to ensure that adequate residence time is available for SO₂ control and to confirm the incremental reduction in SO₂ emissions achievable without creating unacceptable operational issues.

Table 5-5. DSI SO₂ Control Technology Estimated Emissions

	Unit 1
Uncontrolled SO ₂ Emissions (lb/MMBtu)	3.12
SO ₂ Emissions at DSI Outlet (lb/MMBtu)	2.03
SO ₂ Emissions at FF Outlet (lb/MMBtu)	0.58 ¹
Overall Removal (%)	80.4

Note 1. Emissions at the FF outlet were estimate by applying existing 71% SO₂ removal across the DFGD system ((2.03 lb/MMBtu x (1 – 0.71) = 0.58).

Note 2. Emission rates shown represent average emission rates that the control options would be expected to achieve on an on-going long-term basis under normal operating conditions for Coyote Unit 1. Emission rates are provided for comparative purposes, and should not be construed to represent proposed permit limits. Corresponding permit limits must be evaluated on a control system-specific basis; however, an additional 10-15% margin would likely be needed to account for operating margin.

5.1.2.4 FGD Operational Improvements + DSI

Some of the SO₂ control technologies which involve improvements to the FGD can potentially be applied in combination with dry sorbent injection to provide additional SO₂ removal. This option would be considered a layered technology of the technically feasible FGD operational improvements discussed in Section 5.1.2.2 with dry sorbent injection discussed in Section 5.1.2.3. Technically feasible FGD operational improvements include increasing the Ca:S stoichiometric ratio of the FGD by introducing additional fresh lime to the absorber modules. Based on engineering judgement, layering FGD operational improvements with DSI could reduce SO₂ emissions from the baseline SO₂ emission rate of 0.85 lb/MMBtu to approximately 0.33 lb/MMBtu at Coyote Unit 1 as shown in Table 5-6. However, as stated previously, flow modeling and field testing at Coyote Unit 1 would be needed to ensure that adequate residence time is available for SO₂ control and to confirm the incremental reduction in SO₂ emissions achievable without creating unacceptable operational issues.

Table 5-6. Layered (DSI + Ca:S) SO₂ Control Technology Estimated Emissions

	Unit 1
Uncontrolled SO ₂ Emissions (lb/MMBtu)	3.12
SO ₂ Emissions at DSI Outlet (lb/MMBtu)	2.03
SO ₂ Emissions at FF Outlet (lb/MMBtu)	0.33 ¹
Overall Removal (%)	89.4

Note 1. Emissions at the FF outlet were estimate by applying 84% SO₂ removal across the DFGD system with operational improvements ((2.03 lb/MMBtu x (1 - 0.84 lb/MMBtu) = 0.33 lb/MMBtu).

Note 2. Emission rates shown represent average emission rates that the control options would be expected to achieve on an on-going long-term basis under normal operating conditions for Coyote Unit 1. Emission rates are provided for comparative purposes, and should not be construed to represent proposed permit limits. Corresponding permit limits must be evaluated on a control system-specific basis; however, an additional 10-15% margin would likely be needed to account for operating margin.

5.1.2.5 Install New Dry FGD System

Replacing the existing dry scrubber and fabric filter with new control systems would require significant engineering and modifications to the facility. Based on a preliminary review of the facility layout, the new control systems could be located northeast of Coyote Unit 1's existing dry scrubber/FF. The new DFGD/FF and all auxiliary equipment could be constructed while the unit remains on-line. The control systems could be tied-in to the existing systems during a scheduled major outage.

Various DFGD systems have been designed for use with pulverized coal-fired boilers; including the spray dryer absorber (SDA) and circulating dry scrubber (CDS). Both systems are evaluated in more detail below.

Spray Dryer Absorber / Fabric Filter

SDA systems have been used in large coal-fired utility applications, and have demonstrated the ability to effectively reduce uncontrolled SO₂ emissions from pulverized coal units. Like other dry scrubbing systems, SDA control systems use a slurry of lime and water injected into the reaction modules to remove SO₂ from the combustion gases. The reaction modules are designed to provide adequate contact and residence time between the exhaust gas and the slurry to produce a dry by-product. Process equipment associated with an SDA control system includes an alkaline storage tank, mixing and feed tanks, atomizer assembly, spray chamber module, integrated fabric filter, and solids recycle system. The recycle system collects solid reaction byproducts and recycles them back to the spray dryer feed system to maximize reactant utilization.

Various process parameters affect the efficiency of the SDA process including: the type and quality of the additive used for the reactant, reactant-to-sulfur stoichiometric ratio, how close the SDA is operated to saturation conditions, and the amount of solids product recycled to the atomizer. SDA systems are typically designed to operate within approximately 30 °F adiabatic approach to saturation temperature. Operating closer to the adiabatic saturation temperature may allow for higher SO₂ control efficiencies; however, outlet temperatures too close to the saturation temperature will result in severe operating problems including reactant build-up in the absorber modules, blinding of the fabric filter bags, and corrosion in the fabric filter and ductwork.

SO₂ removal efficiencies in a SDA are also dependent upon good gas-to-liquid contact. Reactant spray nozzle designs are vendor-specific, and include both dual-fluid nozzles and rotary atomizers. The atomizing nozzle assembly is typically located in the SDA penthouse and flange mounted to the roof of the absorber vessel.

Replacing the existing dry scrubber/FF with a new SDA/FF control systems is a technically feasible and commercially available control option on Coyote Unit 1. SDA/FF control systems are generally installed on units that burn lower sulfur fuels (i.e., < 3 lb SO₂/MMBtu) because design limitations, including Ca:S stoichiometry, residence time, and approach to saturation typically limit total SO₂ removal to approximately 95%. This removal efficiency represents what the control system vendor would be willing to guarantee upon initial operation of the system. On Coyote Unit 1, 95% removal would result in an average controlled SO₂ emission rate of approximately 0.16 lb/MMBtu.

Circulating Dry Scrubber / Fabric Filter

A second type of dry scrubbing system is the circulating dry scrubber (CDS). Similar to other dry flue gas desulfurization systems, the CDS system would be located after the air preheater, and byproducts from the system collected in an integrated fabric filter. Unlike the SDA systems, CDS systems use a circulating fluidized bed of hydrated lime reagent to remove SO₂ rather than an atomized lime slurry; however, similar chemical reaction kinetics are used in the SO₂ removal process.

In a CDS, flue gas is treated in an absorber vessel where the flue gas stream flows through a fluidized bed of hydrated lime and recycled byproduct. Water is injected into the absorber through a venturi located at the base of the absorber for temperature control. Flue gas velocity through the vessel is maintained to keep the fluidized bed of particles suspended in the absorber. Water sprayed into the absorber cools the flue gas from approximately 300 °F at the inlet to the scrubber to approximately 160 °F at the outlet of the fabric filter. The hydrated lime absorbs SO₂

from the gas and forms calcium sulfite and calcium sulfate solids. Desulfurized flue gas passes out of the absorber, along with the particulate matter (reaction products, unreacted hydrated lime, calcium carbonate, and the fly ash) to the fabric filter.

As with the SDA/FF option, replacing the existing dry scrubber/FF with a new CDS/FF control system would require significant engineering and modifications to the existing facility. For this evaluation it was assumed that the CDS/FF control systems could be located adjacent to the existing dry scrubber/FF, and that the control systems could be tied-in to the existing system during a scheduled major outage.

Replacing the existing dry scrubber and FF with a new CDS/FF control system is a technically feasible and commercially available control option for Coyote Unit 1. Based on engineering judgment, it is anticipated that the retrofit CDS/FF control option would achieve SO₂ removal efficiencies higher than those achieved with a SDA/FF due to the increased Ca:S contact in the fluidized bed absorber vessel. Based on recent CDS retrofit projects, and taking into consideration expected fuel characteristics, it is anticipated that the retrofit CDS/FF control system could achieve SO₂ removal efficiencies of approximately 97%. This removal efficiency represents what the control system vendor would be willing to guarantee upon initial operation of the system. On Coyote Unit 1, 97% removal would result in an average controlled SO₂ emission rate of approximately 0.09 lb/MMBtu and represents an average emission rate that Coyote would be expected to achieve on an on-going long-term basis under normal operating conditions. The emission rate should not be construed to represent proposed permit limits. Corresponding permit limits must be evaluated on a control system-specific basis; however, an additional 10-15% margin would likely be needed to account for operating margin.

5.1.2.6 Install New Wet FGD System

Another option available to the Coyote Station would be to replace the existing dry scrubbing system with a new wet FGD control system located downstream of the existing FF.

Wet FGD technology is an established SO₂ control technology. Wet scrubbing systems have been designed to utilize various alkaline scrubbing solutions including lime, limestone, and magnesium-enhanced lime. Wet scrubbing systems have also been designed with spray tower reactors and with reaction vessels (e.g., jet bubbling reactor). Although the flue gas/reactant contact systems may vary, the chemistry involved in all wet scrubbing systems is essentially identical. All wet scrubbing systems use an alkaline slurry that reacts with SO₂ in the flue gas to form insoluble calcium sulfite (CaSO₃) and calcium sulfate (CaSO₄) salts.

A large majority of the wet FGD systems designed to remove SO₂ from existing high-sulfur utility boilers have been designed as wet limestone scrubbers with spray towers and forced oxidation systems. Therefore, for this evaluation, it was assumed that the WFGD control system would be designed as a limestone spray tower scrubber with forced oxidation. Other potentially available wet scrubber designs are not included in this evaluation because the chemistry involved in all wet scrubbing systems are essentially identical, alternative designs would not provide any additional SO₂ control, and control system costs would be similar.

Wet Limestone Scrubbing

In a wet limestone scrubbing system, limestone (CaCO₃) is mixed with water to formulate the alkali scrubber slurry. Flue gas enters the absorber vessel and contacts the absorbent slurry in a countercurrent spray tower. SO₂ in the flue gas reacts with the limestone slurry to form insoluble calcium sulfite (CaSO₃) and calcium sulfate (CaSO₄) which is removed as a solid waste by-product. Spent absorbent is returned to the reaction tank where dissolved sulfur compounds are precipitated as calcium salts. Fresh limestone slurry is added to regenerate the spent absorbent.

The reaction tank is sized to provide sufficient time for precipitation of the sulfur compounds. From the reaction tank, regenerated absorbent slurry is recycled to the absorber. The slurry typically contains from 5 to 15% suspended solids consisting of fresh additive, absorption reaction products, and lesser amounts of fly ash. To regulate the accumulation of solids, a bleed stream from the reaction is routed to the solid/liquid separation equipment.

Forced oxidation of the scrubber slurry may be used with limestone WFGD systems to produce calcium sulfate solids (gypsum) instead of the calcium sulfite by-product. Air blown into the reaction tank provides oxygen to convert most of the calcium sulfite (CaSO₃) to a relatively pure gypsum. Forced oxidation of the scrubber slurry provides a more stable by-product and reduces the potential for scaling in the spray tower. The gypsum by-product from this process must be dewatered, and may be salable if a local market for gypsum is available, reducing the quantity of solid waste that needs to be landfilled.

For this evaluation it was assumed that the existing Coyote Unit 1 dry scrubber reactor vessels would remain in place, and that the WFGD control system would be located downstream of the existing FFs and ID fans, most likely northeast of the unit's existing dry scrubber/FF. Dry scrubber reactor vessel internals would ultimately be removed to reduce pressure drop through the system. A single WFGD absorber tower would be sufficient for the Coyote

Unit 1 flue gas flow. In addition to the absorber tower and reaction vessel, the WFGD control system would require a limestone handling and preparation system and by-product dewatering systems. Because of the saturated nature of the flue gas exiting the WFGD, a new stack with a liner capable of wet flue gas operation would be required. New booster ID fans would also be required to account for the additional pressure drop through the WFGD control system.

Wet FGD technology is an established SO₂ control technology. Wet scrubbing systems have been installed on units that fire medium to high sulfur coals, and would be a technically feasible SO₂ control option for Coyote Unit 1. Based on engineering judgment and information from control system vendors, it is anticipated that a retrofit WFGD control system on a North Dakota lignite-fired unit would be designed to achieve and SO₂ removal efficiency of approximately 98%. This removal efficiency represents what the control system vendor would be willing to guarantee upon initial operation of the system. On Coyote Unit 1, 98% removal would result in an average controlled SO₂ emission rate of approximately 0.06 lb/MMBtu and represents an average emission rate that Coyote would be expected to achieve on an on-going long-term basis under normal operating conditions. The emission rate should not be construed to represent proposed permit limits. Corresponding permit limits must be evaluated on a control system-specific basis; however, an additional 10-15% margin would likely be needed to account for operating margin.

5.1.2.7 Technical Feasibility Summary

Table 5-7 summarizes the results of the feasibility evaluation of available control options for Coyote Unit 1.

Table 5-7. Technically Feasible SO₂ Control Options

SO ₂ Control Option	Technically Feasible (Yes/No)	Technical Feasibility Summary
Fuel Switching	No	Fuel switching is not considered an available SO ₂ control option for Coyote Unit 1 since the use of North Dakota lignite coal is an inherent aspect of plant operations.
Existing DFGD Operational Improvements:		
Lime Quality	No	Changing lime quality in the existing DFGD control system is not a technically feasible operational change for Coyote Unit 1.
Ca:S Stoichiometric Ratio	Yes	Increasing the Ca:S stoichiometric ratio by increase the quantity of fresh lime to the system is considered a technically feasible option for Coyote Unit 1, assuming the operational change is coupled with atomizer replacement.

SO ₂ Control Option	Technically Feasible (Yes/No)	Technical Feasibility Summary
Approach to Saturation Temperature	No	Due to design limitations, further reducing the absorber module outlet temperature on the existing DFGD control system is not a technically feasible option for Coyote Unit 1.
Existing DFGD Equipment Upgrades:		
Atomizer Replacement	Yes	Replacing the existing atomizers is a technically feasible option for Coyote Unit 1 and would provide additional SO ₂ control if coupled with increasing the Ca:S stoichiometric ratio.
Slaker Replacement	No	Slaker replacement would not be expected to provide additional SO ₂ control, and is not a technically feasible equipment upgrade for Coyote Unit 1.
Adding an Absorber Module	No	Coyote Unit 1 DFGD absorber modules are no longer commercially available, thus, adding an absorber module to the existing system is not a technically feasible SO ₂ control option.
Replacing Existing Absorbers with New Absorber Modules	Yes	Replacing the exiting absorber modules with new absorber modules is a technically feasible SO ₂ control system upgrade for Coyote Unit 1 that would require an approximate 12-month outage.
Existing DFGD + DSI	Yes	Hydrated lime sorbent injection upstream of the existing Coyote Unit 1 absorber modules is a technically feasible SO ₂ control option. Flow modeling and field testing would be needed to confirm that the incremental reduction in SO ₂ emissions is achievable without creating unacceptable operational issues.
Existing DFGD Operational Improvements (Increase Ca:S Stoichiometric Ratio) + DSI	Yes	Combining operational improvements (i.e., increased Ca:S stoichiometric ratio) with hydrated lime sorbent injection is a technically feasible SO ₂ control option for Coyote Unit 1. Flow modeling and field testing would be needed to confirm that the incremental reduction in SO ₂ emissions is achievable without creating unacceptable operational issues.
New Retrofit DFGD (CDS/FF)	Yes	Replacing the existing DFGD control system with a new retrofit DFGD (i.e., CDS/FF) is a technically feasible SO ₂ control option for Coyote Unit 1.
New Retrofit WFGD	Yes	Replacing the existing DFGD control system with a new retrofit WFGD is a technically feasible SO ₂ control option for Coyote Unit 1.

5.1.3 Evaluate Technically Feasible SO₂ Control Options for Effectiveness

The technically feasible SO₂ control technologies are listed in Table 5-8 in descending order of control efficiency. Table 5-8 also provides control option-specific SO₂ emission rates in terms of lb/MMBtu. Emission rates shown in

Table 5-8 represent average emission rates that the control options would be expected to achieve during normal operations.

Table 5-8. Evaluate Technically Feasible SO₂ Control Options for Effectiveness

Control Option	SO ₂ Emission Rate (Note 1) lb/MMBtu	% Reduction from Baseline Emission Rate
Baseline (existing DFGD/FF)	0.85	-
New Retrofit WFGD	0.06	92.9%
New Retrofit DFGD (CDS/FF)	0.09	89.4%
New Retrofit DFGD (SDA/FF)	0.16	81.1%
FGD Upgrades - Replacing Existing Absorbers with New Absorber	0.29	65.9%
DSI + FGD Operational Improvements	0.33	61.2%
FGD Operational Improvements – Increase Ca:S Stoichiometric Ratio	0.50	41.2%
DSI + Existing FGD	0.58	31.8%

Note 1. Emission rates shown in Table 5-8 represent average emission rates that the control options would be expected to achieve on an on-going long-term basis under normal operating conditions for Coyote Unit 1. Emission rates are provided for comparative purposes, and should not be construed to represent proposed permit limits. Corresponding permit limits must be evaluated on a control system-specific basis; however, an additional 10-15% margin would likely be needed to account for operating margin.

5.2 NO_x EMISSIONS CONTROLS

5.2.1 Identify Available NO_x Control Options

Based on a review of available NO_x control technologies installed on existing cyclone coal-fired boilers, as well as operational practices and equipment upgrades implemented on existing control systems, potentially available options to control NO_x emissions from Coyote Unit 1 are listed in Table 5-9.

Table 5-9. Available NO_x Control Options

NO _x Control Technologies
Combustion Optimization
Selective Non-Catalytic Reduction (SNCR)
Rich Reagent Injection (RRI)
SNCR + RRI
Gas Reburn
Innovative Technologies (i.e. NOxStar, Water Injection, LoTOX, PerNOxide, Water Injection)
Selective Catalytic Reduction - High Dust, Low Dust or Tail End Configuration (TE-SCR)

5.2.2 Technical Feasibility of Available NO_x Control Options

Potentially available NO_x control options identified in Table 5-9 were evaluated for technical feasibility (i.e. availability and applicability to Coyote Unit 1) based on a review of physical, chemical, and engineering principals, and an assessment of commercial availability. Options deemed to be technically infeasible, or options that have no practical application to Coyote Unit 1, were eliminated from further review. S&L evaluated the effectiveness of the control options determined to be technically feasible, and established an emission performance level (i.e., controlled emission rate) for each.

5.2.2.1 Combustion Optimization

Coyote Unit 1 is equipped with twelve (12) ten (10) foot cyclones, six (6) on the front wall and six (6) each on the rear wall, two levels of three on each wall. The lignite coal requires a pre-dry system, which conveys the coal through individual crushers and into a cyclone separator for moisture separation. The dried coal is discharged from the bottom of the separator through a rotary seal, while the transport air (with a small quantity of fines) is discharged out the top and into ports above the cyclones. The coal discharged through the bottom rotary seal is blown into the cyclone through a pipe referred to as the “lift line” or known as primary air on most other similar installations. The temperature of the pre-dry air/coal temperature is regulated along with the lift line air by injecting cold (tempering) air into the hot primary air stream to regulate the outlet temperatures.

In 2016, The Babcock and Wilcox Company (B&W) installed fourteen (14) separated overfire air (SOFA) ports (seven on the front and rear wall) and modified the cyclones with smaller re-entrant throats and a $\frac{1}{3} - \frac{2}{3}$ split secondary air damper (each having its own damper) to reduce NO_x emissions. For the SOFA process, the injection of air into the boiler is staged into two zones, in which approximately 5% to 20% of the total combustion air is diverted from the burners and injected through ports located above the top burner level. Staging of the combustion air reduces NO_x formation by two mechanisms. First, staged combustion results in a cooler flame which will reduce the formation of thermal NO_x. Second the staged combustion results in less oxygen reacting with fuel molecules. The degree of staging is limited by operational problems since the staged combustion results in incomplete combustion conditions and a longer flame profile. The units normally operate with the $\frac{1}{3}$ rd damper closed or nearly closed to help recirculate the coal in the cyclone and allows for increased coal retention and improved combustion. Since the SOFA installation, Coyote Unit 1 has achieved average controlled NO_x emissions of approximately 0.46 lb/MMBtu.

Tuning of the cyclone boiler to optimize the combustion process and minimize the generation of NO_x was recently completed at Coyote Unit 1. Tuning was completed by lowering the stoichiometry (i.e., lower the air-to-fuel ratio) in the cyclone barrel and tracking the cyclone combustion stability, while staying within the OEM specifications for best combustion engineering practice. Based on the testing results, Coyote Unit 1 was able to achieve average NO_x emissions of approximately 0.42 lb/MMBtu without obvious impacts to boiler performance and with minimal slagging. Based on the results of the combustion turning tests, combustion optimization is considered a technically feasible NO_x control option.

5.2.2.2 Selective Non-Catalytic Reduction

Selective non-catalytic reduction (SNCR) involves the direct injection of ammonia (NH₃) or urea (CO(NH₂)₂) at high flue gas temperatures (approximately 1,600°F – 2,100°F) in an oxidizing environment. The ammonia or urea reacts with NO_x in the flue gas to produce N₂ and water as shown below.

Flue gas temperature at the point of reagent injection can greatly affect NO_x removal efficiencies and the quantity of NH₃ or urea that will pass through the SNCR unreacted (referred to as NH₃ slip). In general, SNCR reactions are effective in the range of 1,600°F – 2,100°F. At temperatures below the desired operating range, the NO_x reduction

reactions diminish and unreacted NH_3 emissions increase. Above the desired temperature range, NH_3 is oxidized to NO_x resulting in low NO_x reduction efficiencies.

Mixing of the reactant and flue gas within the reaction zone is an important factor to SNCR performance. In large boilers, the physical distance over which reagent must be dispersed increases, and the surface area/volume ratio of the convective pass decreases. Furnace geometry, urea spray coverage, and droplet size must be considered when developing good mixing of reagent and flue gas, delivery of reagent in the proper temperature window, and sufficient residence time of the reagent and flue gas in that temperature window. As the boiler cycles in load, the optimum injection region may change; thus, most facilities require multiple injection zones which are placed in and out of service as the unit ramps in load. This can include modifying the zones of injectors that are operating at different loads and temperatures.

Retractable multinozzle lances (MNLs) are sometimes used to improve SNCR performance, especially if the furnace exit flue gas temperatures are too high. The retractable lances allow injection into the appropriate temperature zone more so than wall injectors, depending on the unit load and temperatures. The MNLs also help improve performance by refining the spray pattern for quicker vaporization of the conveying water. MNLs are often used in conjunction with wall injection to provide optimized coverage while reducing reagent cost.

In addition to temperature and mixing, several other factors influence the performance of an SNCR system, including residence time, reagent-to- NO_x ratio, and fuel sulfur content. Increasing the normalized stoichiometric ratio (NSR) can improve NO_x removal.²⁵ This can be achieved by increasing urea solution flow through the injectors or changing the concentration of urea in the solution. However, too high of reagent injection rates will increase the ammonia slip beyond the recommended 10 ppmvd limit. Above this concentration, there are expected to be major impacts to the formation of ammonia salts on the boiler tube banks, reducing heat transfer efficiency, and air heater baskets, causing corrosion.

SNCR can be applied on cyclone boilers due to having reasonable temperature windows and residence time; however, the potential NO_x reduction is boiler-specific. SNCR has been used as a retrofit NO_x control system of on pulverized coal, fluidized bed boilers, and cyclone boilers. Furthermore, SNCR can be implemented on boilers

²⁵ NSR defines the amount of reagent needed to achieve the targeted NO_x reduction. Based on the reaction equations in 5.2.2.2, two moles of NO_x can be removed with one mole of urea or two moles of ammonia. In practice, more than the theoretical amount of reagent needs to be injected into the boiler flue gas to obtain a specific level of NO_x reduction. This is due to the complexity of the actual chemical reactions involving NO_x and injected reagent and mixing limitations between reagent and flue gas. Factors that influence the NSR value: (1) percent NO_x reduction; (2) uncontrolled NO_x concentration in the flue gas; (3) temperature and residence time available for the NO_x reduction reactions; (4) extent of mixing achievable in the boiler; and (5) allowable ammonia slip.

equipped with low-NO_x burners, overfire air, or SOFA systems. Based on the boiler residence time, temperature profile, and stoichiometry, as well as input from SNCR OEMs, it is estimated that an SNCR system could achieve an average controlled NO_x emission rate of approximately 0.28 lb/MMBtu (approximately 39% below the baseline emission rate of 0.46 lb/MMBtu) at full load while limiting ammonia slip to 10 ppmvd. It should be noted that computational fluid dynamic modeling and temperature mapping of the boiler would be needed to confirm that the incremental reduction in NO_x emission is achievable without creating unacceptable operational issues.

5.2.2.3 Rich Reagent Injection

Similar to SNCR, the concept of rich reagent injection (RRI) is to use a nitrogen-containing additive (e.g., urea) injected into a reducing environment to promote NO_x removal. RRI is a commercial technology for cyclone boilers only. In contrast to SNCR, RRI typically is applied with only one injection level in the lower furnace near the cyclone barrels (temperature window of 2000°F-2600°F). The technology requires a sub-stoichiometric oxygen concentration near the barrels at less than approximately 0.95. This allows for a higher injection rate of reagent without oxidizing the nitrogen-containing reagent to NO_x due to the sub-stoichiometry. Injection at this location also creates lower level of excess NH₃ emissions (NH₃ slip), while injecting at an NSR of 2.0-3.0.

Due to the changes of the lower furnace stoichiometry, RRI is often not a technically feasible option at low loads. Once the stoichiometric ratio increases to >1.0, the potential exists for NO_x generation due to the reaction of NH₃ with oxygen, especially if the injection location and rate is not optimized. Based on these limitations, RRI is considered most effective at full load.

The RRI process is a commercially available process. Based on engineering judgment, RRI is expected to reduce NO_x emissions by approximately 20-40% at Coyote Unit 1 when operating at full load with minimal ammonia slip. However, due to the cyclone combustion temperature window, this technology only provides effective NO_x reduction at or near full load. At low loads, RRI does not provide effective control; however, RRI can be combined with SNCR to provide NO_x control across the full range of normal operating loads. RRI is a technically feasible NO_x reduction option for North Dakota lignite-fired cyclone boilers. However, due to its limited operating conditions and ineffective NO_x reduction at low loads, RRI alone is not considered an available NO_x control option, and will only be evaluated in conjunction with SNCR.

5.2.2.4 SNCR + RRI

While RRI alone will provide beneficial NO_x reduction at full load only, coupling RRI with SNCR can provide a balanced approach to NO_x reduction through all load ranges. Since RRI and SNCR injectors are located at different elevations of the furnace and in different temperature windows, there are not concerns of spatial impacts. The combined system would utilize a relatively high urea injection rate, staged at multiple locations throughout the boiler. The main advantage of this combined system is that the SNCR can provide better NO_x reduction at low load and at a lower NSR than RRI alone; thus, the combined system is expected to provide effective NO_x control across all normal operating load ranges. Coupling RRI and SNCR is considered a technically feasible and commercially available NO_x control technology option on Coyote Unit 1. Based on input from SNCR OEMs and engineering judgment, the control option is expected to achieve an average outlet NO_x rate of approximately 0.20 lb/MMBtu with an ammonia slip of 10 ppmvd. It should be noted that computational fluid dynamic modeling and temperature mapping of the boiler would be needed to confirm that the incremental reduction in NO_x emission is achievable without creating unacceptable operational issues.

5.2.2.5 Gas Reburn

Gas reburn is a retrofit technique that has been used to control NO_x emissions from coal- and oil-fired boilers. Gas reburn involves combustion in three distinct zones within the boiler: (1) a primary combustion zone, where the primary fuel is fired using conventional burners; (2) a reburn zone, where secondary fuel, typically natural gas, is introduced into the boiler; and (3) an OFA burnout zone.

In the primary zone of coal-fired boilers, coal is fired through low-NO_x burners (LNBs), at a rate corresponding to approximately 80% to 90% of the total heat input. Natural gas reburn fuel is then injected above the primary combustion zone under fuel-rich conditions at a rate corresponding to approximately 10% to 20% of the total heat input (on a Btu/hour basis). The fuel-rich reburn zone creates a reducing (substoichiometric) region within the boiler where the natural gas, principally methane (CH₄), breaks down to produce hydrocarbon radicals (CH and CH₂). The hydrocarbon radicals react with NO_x produced in the primary combustion zone to form nitrogen (N₂) and water vapor. Because the natural gas is not completely combusted in the reburn zone, gases exiting the reburn zone will contain considerable CO and unburned hydrocarbons; therefore, additional OFA is introduced above the reburn zone to complete the combustion process.

Critical design parameters that affect the feasibility and performance of a gas reburn retrofit system include: (1) baseline NO_x concentration; (2) reburn zone temperature, residence time, and stoichiometry; (3) OFA burnout zone temperature and residence time; and (4) mixing of the reburn fuel and overfire air with the bulk flue gas.

Gas reburn can have a positive impact on NO_x emissions; however, in order to make a meaningful prediction of the NO_x removal capabilities at Coyote Unit 1, extensive testing would be required because gas reburn performance is significantly dependent upon boiler operating characteristics. More importantly, the lack of natural gas available at the Coyote Station precludes the ability to test and implement this control option on Coyote Unit 1. For these reasons, gas reburn is not considered an available or technically feasible NO_x control technology at Coyote Unit 1.

5.2.2.6 Innovative Technologies

NO_xStarTM

The NO_xStarTM process, also known as selective autocatalytic reduction (SACR), uses a continuous controlled amount of ammonia-based reagent with relatively small amounts of hydrocarbon to reduce NO_x emissions. The hydrocarbon is introduced into the flue gas at the convective pass of the boiler, at elevated temperatures. At the elevated temperatures, the hydrocarbon auto-ignites to form a plasma of free radicals that auto catalyzes the reaction of NH₃ and NO_x to form N₂ and H₂O. The hydrocarbon and ammonia are added through banks of nozzles in the superheat or reheat sections of the boiler. The injection location is determined by the location of the temperature windows for the "plasma creation zone" as well as the reaction zone for the ammonia.

To date, only one full-scale demonstration has been conducted to evaluate the technology on a utility-sized boiler. The process is an emerging NO_x control, and there is limited information available to evaluate its technical feasibility and long-term effectiveness on a large lignite-fired boiler. Potential NO_x removal efficiencies would be a function of NH₃-NO_x mixing, flue gas temperature, flue gas composition, and residence time downstream of the injection lances.

Because this is an emerging technology, extensive design engineering and long-term full scale demonstration testing would be required to evaluate the technical feasibility and effectiveness of the control system on Coyote Unit 1. Detailed design of the lances, mixing, optimization of the reagent supply across the boiler convective pass, flue gas temperatures, and flow distribution would have to be studied. Interference with the tube pendants in the convective pass may also make this more difficult to install. Installing a hydrocarbon distribution grid may

present a problem with large boilers because of the span needed to uniformly distribute the reagent, interference with the tube pendants in the convective pass, and an additional booster fan may be needed. For these reasons, NO_xStar™ is not considered an available or technically feasible NO_x control technology at Coyote Unit 1.

PerNO_xide

PerNO_xide utilizes hydrogen peroxide (H₂O₂) to reduce NO_x emissions. Hydrogen peroxide is injected into the ducts ahead of the air preheater and oxidizes the NO to NO₂, which is then captured in a downstream FGD system. To date, the technology has only been tested on a pilot-scale, and it has not been demonstrated on any coal-fired boilers. It is likely that extensive design engineering and testing would be required to evaluate the scale-up potential and long-term effectiveness of the system on Coyote Unit 1. For these reasons, PerNO_xide is not considered an available or technically feasible NO_x control technology at Coyote Unit 1.

LoTO_x®

The LoTO_x system is a gas-phase, low-temperature oxidation system, wherein ozone is injected into the flue gas stream to oxidize NO and NO₂ to N₂O₅ before being removed in a wet scrubber. This highly oxidized species of NO_x is water-soluble and rapidly reacts with water to form nitric acid. The conversion of NO_x to nitric acid occurs as the N₂O₅ contacts liquid sprays in the scrubber. The nitric acid would react with the alkali compounds in the scrubber and would be eliminated via the scrubber waste and byproduct streams. The LoTO_x system requires on-demand ozone generation from a liquid oxygen supply.

The LoTO_x system has been successfully applied in refinery applications; however, there are no full scale installations on coal-fired boilers. According to the control system vendor, a demonstration test was performed on a 25-MW coal-fired boiler which showed effective NO_x removal. However, it is likely that extensive design engineering and testing would be required to evaluate the scale-up potential and long-term effectiveness of the system on Coyote Unit 1. As such, LoTO_x is not considered an available or technically feasible NO_x control technology at Coyote Unit 1.

Water Injection

The principle behind this technology is to inject an atomized water spray into the high-NO_x production zones of a cyclone burner or in the core of the flame for other furnaces. The water spray reduces the temperature and results in lower thermal NO_x production within this combustion zone. Developers claim that water injection through

burners used in tangential-fired and wall-fired units will also reduce flame temperatures and lower thermal NO_x production. However, to date only bench-scale test results are available to evaluate this technology's effectiveness in coal-fired applications. Extensive design engineering, pilot-scale testing, and long-term full scale demonstration testing would be required to evaluate the technical feasibility and effectiveness of the control system on Coyote Unit 1.

Water injection has been used to control the formation of thermal NO_x in combustion turbine applications. However, there is insufficient experience and demonstration data in coal-fired applications. As such, water injection is not considered an available or technically feasible NO_x control technology at Coyote Unit 1.

5.2.2.7 Selective Catalytic Reduction

SCR is a process by which ammonia reacts with nitric oxide (NO) and nitrogen dioxide (NO₂), collectively NO_x, in the presence of a catalyst to reduce the NO_x to nitrogen (N₂) and water. SCR technology has been applied to NO_x-bearing flue gases generated from power generating facilities burning various types of coal, including bituminous, subbituminous, and Texas lignite. The principal reactions resulting in NO_x reduction are:

Because these reactions proceed slowly at typical boiler exit gas temperatures of a coal-fired steam electric generating unit, a catalyst is used to increase the reaction rate between NO_x and ammonia. Depending on the specific constituents in the flue gas, a typical temperature range of 550°F to 780°F is necessary to achieve normal performance of the catalyst. For the typical coal-fired boiler, optimal performance will be in the range of approximately 650°F to 750°F.

In general, there are three candidate SCR configurations that can be employed on coal-fired steam electric generating units. The SCR configuration designations generally describe the location of the SCR reaction vessel in relation to other post-combustion air quality control systems. Candidate SCR configurations include:

- High-dust configuration
- Low-dust configuration
- Tail-end configuration

Each of these configurations is described below as they would be applied at Coyote Unit 1.

High-Dust Configuration

In a high-dust configuration, the SCR reactor is located in the flue gas stream between the economizer outlet and the air heater inlet. This configuration locates the SCR within the inherently optimal temperature range environment for NO_x reduction (i.e., 650°F to 750°F); however, flue gas characteristics at the economizer outlet can also have detrimental effects on the SCR catalyst. As an example, the high-dust SCR configuration exposes the SCR catalyst to high levels of fly ash loading. High levels of fly ash can result in significant erosion of the catalyst, resulting in more frequent cleaning cycles and catalyst replacement. A second major concern with the high-dust configuration at Coyote Unit 1 is the presence of high levels of sodium (both in the vapor-phase and as submicron aerosols) in the North Dakota lignite-derived flue gas. Sodium is a known SCR catalyst poison, and also affects the adhesive and cohesive characteristics of the fly ash, which in turn, would have an adverse effect on the SCR catalyst and reactor vessel.

SCR catalyst deactivation occurs through two primary mechanisms: physical deactivation and chemical poisoning. Physical deactivation is caused by either exposure of the catalyst to excessive temperatures (thermal deactivation) or masking of the catalyst due to entrainment of particulate from the flue gas stream (fouling). Chemical deactivation is caused by either an irreversible reaction of the catalyst with a contaminant in the gas stream (poisoning) or a reversible absorption of a contaminant on the surface of the catalyst (inhibition). Loss of catalyst activity through thermal degradation or poisoning is permanent, and reactivity can only be restored by replacing the catalyst.

In a North Dakota lignite application, SCR catalyst poisoning is expected to result from the presence of trace elements and strong alkaline substances in flue gas, including sodium (Na), potassium (K), and calcium (Ca). Alkaline metals can chemically attach to active catalyst pore sites and cause deactivation. Sodium and potassium are of prime concern especially in their water-soluble forms, which are more mobile and can penetrate into the catalyst pores. Earth metals, especially calcium, can react with SO₃ absorbed within the catalyst to form CaSO₄ and blind the catalyst.

North Dakota lignite contains relatively high levels of organically associated alkali and alkaline-earth elements, including Na, Ca, K, and magnesium. Sodium levels in North Dakota lignite are typically 5 to 20 times higher than sodium levels in bituminous and subbituminous coals, and sodium compounds can represent between 5% and 11% of the ash generated from firing North Dakota lignite. These sodium levels, occurring in both the vapor phase and particulate phase, along with relatively high levels of potassium and calcium, significantly increase the potential for

catalyst deactivation, plugging, and erosion. Based on the ash chemistry, a conventional high dust SCR arrangement would likely experience unacceptable catalyst deactivation rates.

To evaluate deactivation rates on a North Dakota lignite-fired boiler, EERC and several utilities and catalyst vendors conducted pilot scale testing at the Coyote Station in 2003-2004. The pilot scale test reactor SCR deployed at the Coyote Station became plugged and the catalyst pores deactivated after 2 months of operation (approximately 1,430 hours). This deactivation rate is significantly faster than the deactivation rate observed on bituminous and subbituminous coal-fired units, which can achieve catalyst life ranging between 10,000 and 30,000 operating hours. The EERC described the deactivation at the Coyote Station as extremely rapid and severe.²⁶

NDDH prepared a comprehensive technical feasibility assessment of high dust SCR on lignite-fired boilers during the first planning period.²⁷ The Department concluded, based on the unique characteristics of North Dakota lignite-derived flue gas, that the high-dust SCR configuration was not a technically feasible or commercially available NOx control option for North Dakota lignite-fired boilers.²⁸ Reasons upon which NDDH based its conclusion that high-dust SCR was not a technically feasible option for North Dakota lignite-fired boilers included, but were not limit to:²⁹

- 1) North Dakota lignite³⁰ has a higher organic matter content and contains a higher proportion of alkali metal constituents, especially sodium, than subbituminous coal. Approximately 75% of the total sodium in lignite is associated with the organic fraction of the lignite. During combustion, organic and water-soluble sodium vaporizes; consequently, combustion of the coal leads to higher flue-gas concentrations of alkali metals in vapor form.
- 2) The unburned or partially burned organic fraction of North Dakota lignite contains more sodium than other coals. Sodium can react with silicate particles causing a “stickiness” quality to the flue gas ash, resulting in increased ash deposition on heat transfer surfaces. Larger particles can fracture from heat-transfer surfaces (a.k.a. popcorn ash) and enter the flue gas stream. Consequently, deposition on surfaces of catalytic reactors occurs and rates of deposition are higher.
- 3) NOx reduction occurs on the flat surfaces of a catalyst and in pores within the flat surfaces. The pores are open to the flue gas passing through the catalyst reactor. Condensed vapors, alkali sulfates and alkaline-earth oxides and silicates are minute particles (less than 1 microns), which enter pores of the catalyst (a.k.a. plugging) and prevent catalytic reaction with NOx. Residual alkali vapors (Na, K, and Ca) displace hydrogen on fresh catalyst, which prevents catalytic reaction with NOx (a.k.a poisoning) and reacts with

²⁸ Id. at pg. 19.

²⁹ Findings and conclusions are summarized from the North Dakota Regional Haze SIP, Appendix B.5, pgs. 15-19.

³⁰ Although the BART determination specifically references Fort Union lignite, the findings would apply to all North Dakota lignites.

sulfate to cause blinding of catalyst surfaces. Pore condensation of sodium also causes catalyst deactivation, which is a major deactivation mechanism. The rate of catalyst deactivation depends on the concentration and form of alkali in the flue gas; higher Na and K accelerate catalyst poisoning, blinding and plugging.

- 4) During the development of the initial planning period SIP, NDDH found that there were no SCR systems planned, constructed, or operating in the flue gas stream of boilers fired with North Dakota lignite. North Dakota lignite has certain coal characteristics that are uniquely different than Texas or Gulf Coast lignites, such as the larger proportion of organic matter and association of alkali, sodium specifically, with that organic matter.
- 5) Slipstream SCR reactors of the same design were installed at three power plants to test SCR for NO_x emissions control. One of the plants was cyclone fired with North Dakota lignite and the others with subbituminous coal. Deposition on the reactor surface after two months using the lignite was significantly greater; the deposits were rich in sodium, calcium, and sulfur. The tests confirmed catalyst blinding and plugging, but did not provide rates for catalyst deactivation. Tests also indicated that the deposits causing blinding and plugging of pores contained more sodium compared to PRB coal.

Based on a review of SCR installations on coal-fired boilers and a review of reported advances in SCR catalysts since the first planning period, deactivation rates due to soluble alkali compounds in the flue gas (including soluble sodium and potassium compounds) and the adhesive/cohesive characteristics and potential abrasive qualities of the North Dakota lignite-derived fly ash remain a concern for North Dakota lignite-fired boilers. SCR has not been installed and successfully operated on a North Dakota lignite-fired boiler, and the bench scale and pilot-scale studies needed to better understand ash behavior and catalyst blinding/erosion with North Dakota lignite-derived fly ash, and to better understand catalyst deactivation mechanisms associated with high soluble alkali compound concentrations in the flue gas have not been required or completed. Pilot-scale studies are needed to evaluate these issues to inform the development of advanced catalyst formulations, and to support the engineering and design studies needed to mitigate for potential deactivation routes (e.g., removing soluble alkali compounds from the flue gas and SCR design considerations such as catalyst formulation, catalyst pitch, reactor velocity, and catalyst surface and volume). Pilot-scale tests and engineering/design studies have not advanced since the first planning period's exhaustive analysis.

These issues have not been resolved since the first planning period and remain a significant barrier to the design and successful operation of high dust SCR on North Dakota lignite-fired boilers. The BART Guidelines state that “[a] control technique is considered available...if it has reached the stage of licensing and commercial availability.”³¹ Commercial availability follows bench scale and laboratory testing and pilot scale testing. Consequently, the BART Guidelines state that “you would not consider technologies in the pilot scale testing stages

³¹ 40 CFR Part 51 Appendix Y, Section D.2.1.

of development as ‘available’ for purposes of BART review.”³² Furthermore, source owners/operators are not expected to conduct extended trials to learn how to apply a technique on a dissimilar source type.³³ These BART guidelines also apply as a recommendation for the development of the LTS in the second planning period and the four factor analysis.³⁴ Because there are unresolved issues associated with catalyst poisoning, catalyst blinding and plugging, and catalyst erosion; and engineering solutions have not been determined or demonstrated and the high dust configuration has not moved beyond pilot scale testing, high dust SCR is not an available technically feasible NOx control technology for Coyote Unit 1.

Low-Dust Configuration

In the low-dust configuration, the SCR reactor vessel is located in the flue gas stream after the particulate collection device (i.e. ESP or FF). Employing this configuration would represent a relatively low level of exposure to fly ash (with the exception of submicron ash particles), but a potentially high level of vapor-phase alkalis, such as sodium. This configuration can be used on units equipped with particulate control only or units equipped with particulate control followed by a WFGD control system. The existing dry FGD/FF control configuration at Coyote Unit 1 for SO₂ and particulate control would preclude the application of a low-dust SCR configuration since, by definition, the SCR would have to be located downstream of both the dry FGD and FF. At that location the SCR would be more appropriately defined as a tail-end SCR configuration, which is described in more detail in the following section. Because Coyote Unit 1 is equipped with existing dry FGD/FF controls, low-dust SCR has no practical application on the unit, and low-dust SCR is not considered a technically feasible NOx control option for Coyote Unit 1.

Tail-End Configuration

In the tail-end configuration, the SCR reaction vessel is located in the flue gas stream after the particulate and FGD control systems. The potential advantage of a tail-end SCR configuration at Coyote Unit 1 is that the flue gas will have passed through the dry FGD/FF system prior to the SCR catalyst. As such, there is the possibility that the mass transfer mechanism that results in the capture of SO₂ will also capture some of the vapor-phase sodium and the sodium-enriched submicron particles, reducing the risk of catalyst poisoning and/or deactivation.

³² Id.

³³ Id.

³⁴ See, Draft EPA Guidelines, pg. 183.

Successful operation of the tail-end configuration would also require a capital and operating cost-intensive gas-to-gas heat exchanger to reheat the flue gas from approximately 200 °F downstream of the existing FF to approximately 550°F to support the SCR NO_x reactions. After the flue gas passes through the SCR (at approximately 550°F), it would pass through the hot side of the gas-to-gas heat exchanger to cool the flue gas to 150°F prior to the exhaust stack. Although this stack gas temperature would be lower than the current stack temperature (190-210°F), it is still higher than the adiabatic saturation temperature of the flue gas (i.e., approximately 135°F). As such, it is likely that the existing stack could be reused without any major modifications.

During the first planning period, NDDH initially concluded, based on preliminary information provided by SCR catalyst vendors, that the tail-end SCR configuration would be a technically feasible option for units firing North Dakota lignite that are subject to BART requirements.³⁵ However, as part of the Milton R. Young Station (MRYS) NO_x BACT determination process, detailed information describing the expected ash characteristics and flue gas characteristics was provided to two SCR catalyst vendors (CERAM Environmental, Inc. (CERAM) and Haldor Topsoe, Inc.). Based on their review of the data, both vendors concluded that they would not be able to provide a catalyst life guarantee for either low-dust or tail-end SCR without pilot-scale testing.³⁶

Both vendors also made statements bringing into question the technical feasibility of either low-dust or tail-end SCR. For example, CERAM stated that the high levels of sodium oxide (Na₂O) in the ash for North Dakota lignite are not commonly found in subbituminous and bituminous coals which are fired in boilers equipped with SCR systems, and that it was unaware of any SCR application experience in the industry with the level and form of sodium in the North Dakota lignite-derived MRYS ash.³⁷

Based in part on this information provided by SCR design engineering firms and SCR catalyst vendors, NDDH concluded that the use of SCR technology, including low-dust and tail-end SCR, on the lignite-fired MRYS boilers would be technically infeasible.³⁸

Based on a review of SCR installations on coal-fired boilers, and a review of reported advances in SCR catalysts since the first planning period, deactivation rates due to soluble alkali compounds in the flue gas (including soluble sodium and potassium compounds) remain a concern for all North Dakota lignite-fired boilers. Tail-end SCR has not been demonstrated or installed on a North Dakota lignite-fired boiler, and there are still significant technical

³⁵ See, North Dakota Regional Haze State Implementation Plan for Regional Haze, February 24, 2010, Appendix B.5, pg. 25.

³⁷ *Id.*, at 1115-1116.

³⁸ *Id.*, at 1118.

concerns associated with the availability of existing SCR catalysts on a North Dakota lignite-fired unit. Catalyst in a tail-end SCR will still be vulnerable to alkali poisoning, pore pluggage, and premature catalyst deactivation, and it is not known whether the comparatively high levels of soluble sodium and potassium in North Dakota lignite will be effectively removed by the upstream dry FGD/FF. Furthermore, the potential exists for fine particulate remaining in the flue gas to get into the catalyst pores reducing catalyst activity. Pilot-scale studies needed to better understand catalyst deactivation mechanisms associated with high soluble alkali compound concentrations in the flue gas have not been completed.

In order to understand the effect of North Dakota lignite-derived flue gas on the tail-end SCR catalyst, identify potential design solutions, and evaluate the technical feasibility and effectiveness of tail-end SCR at Coyote Unit 1 with any degree of certainty, extended pilot scale testing of the control configuration would be needed. Additionally, because there are unresolved issues associated with catalyst poisoning, it's unlikely that OTP could obtain a viable commercial offering for tail-end SCR on Coyote Unit 1. Therefore, tail-end SCR is not an available technically feasible NO_x control technology.

SCR Summary

During the first planning period NDDH determined that high-dust SCR and tail-end SCR are not available, and thus, not a technically feasible NO_x control option for North Dakota lignite-fired boilers. The administrative record developed during the first planning period, including the BART determinations and MRYS BACT analysis, supports the conclusion that high-dust SCR and tail-end SCR are not an available NO_x control option for Coyote Unit 1. An evaluation of SCR installations and reported advances in SCR catalysts since the first planning period, coupled with the fact that high-dust SCR and tail-end SCR have not been demonstrated on a North Dakota lignite-fired boiler, and the likelihood that OTP could not obtain a viable commercial offering for tail-end SCR without extended pilot-scale testing, continues to support the conclusion that high-dust SCR and tail-end SCR are not available NO_x control technologies. Nevertheless, since tail-end SCR cost data was developed by the NDDH for Coyote Unit 1 in the first planning period³⁹, even though tail-end SCR is a technically infeasible technology, it will be carried forward to the Four Factor Analysis to evaluate hypothetical cost-effectiveness. Based on controlled NO_x emissions achieved in practice at existing bituminous- and subbituminous-fired unit, S&L assumed that the

³⁹ See North Dakota State Implementation Plan for Regional Haze, February 24, 2010, Table 9.8. Notably, this cost data was developed prior to the final MRYS BACT determination in which the NDDH concluded tail-end SCR was technically infeasible.

hypothetical tail-end SCR control option could achieve an average controlled NO_x emission rate of 0.09 lb/MMBtu.

5.2.2.8 Technical Feasibility Summary

Table 5-10 summarizes the results of the feasibility evaluation of available control options for Coyote Unit 1.

Table 5-10. Technically Feasible NO_x Control Options

NO _x Control Option	Technically Feasible (Yes/No)	Technical Feasibility Summary
Combustion Optimization	Yes	Tuning to optimize the existing combustion system, including lower the stoichiometry in the cyclone barrels, tracking cyclone combustion stability, and adjusting the SOFA system (while staying within original OEM specifications) is a technically feasible NO _x control option.
Selective Non-Catalytic Reduction (SNCR)	Yes	SNCR is considered an available and technically feasible NO _x control technology for Coyote Unit 1. Computational fluid dynamic modeling and temperature mapping of the boiler would be needed to confirm that the incremental reduction in NO _x emissions is achievable without creating unacceptable operational issues.
Rich Reagent Injection (RRI)	No	RRI is considered an available and technically feasible NO _x control option cyclone burners at full load operation; however, at low load operation RRI does not provide effective NO _x control. Therefore, RRI alone is not considered an available NO _x control option, and will only be evaluated in conjunction with SNCR.
SNCR + RRI	Yes	Coupling RRI and SNCR is considered a technically feasible and commercially available NO _x control technology option on Coyote Unit 1. Computational fluid dynamic modeling and temperature mapping of the boiler would be needed to confirm that the incremental reduction in NO _x emissions is achievable without creating unacceptable operational issues.
Gas Reburn	No	The lack of natural gas availability at the Coyote Station precludes the ability to test and implement this control option on Coyote Unit 1. Therefore, gas reburn is not considered an available or technically feasible NO _x control technology at Coyote Unit 1.
Innovative Technologies: NO _x Star™ PerNO _x ide LoTO _x Water Injection	No	Innovative NO _x control technologies are evaluated in Section 5.2.2.6. In all cases, the technologies have not been demonstrated on a large North Dakota lignite-fired boiler. Extensive testing and design engineering would be required to evaluate the technical feasibility and long-term effectiveness of each innovative control system on Coyote Unit 1. Therefore, the innovative NO _x control technologies are not considered available control options and are not technically feasible NO _x control options for Coyote Unit 1

NO _x Control Option	Technically Feasible (Yes/No)	Technical Feasibility Summary
Selective Catalytic Reduction (SCR):		
High-dust configuration	No	Due to significant unresolved issues associated with catalyst poisoning, catalyst blinding and plugging, and catalyst erosion; and based on the finding that engineering solutions have not been determined or demonstrated and the high dust configuration has not moved beyond pilot scale testing, high dust SCR is not and available or technically feasible NO _x control technology for Coyote Unit 1.
Low-dust configuration	No	Because Coyote Unit 1 is equipped with existing dry FGD/FF control systems, low-dust SCR has no practical application on the unit, and low-dust SCR is not considered an available or technically feasible NO _x control option for Coyote Unit 1.
Tail-end configuration	No	Based on the continued lack of demonstration testing and commercial guarantees, tail-end SCR is considered to be a technically infeasible control option for Coyote Unit 1. Nevertheless, it will be carried forward to the four factor analysis to present hypothetical costs since tail-end SCR was included in the reasonable progress analysis for Coyote Unit 1 during the first planning period.

5.2.3 Evaluate Technically Feasible NO_x Control Options for Effectiveness

The technically feasible NO_x control technologies are listed in Table 5-11 in descending order of control efficiency. Table 5-11 also provides control option-specific NO_x emission rates in terms of lb/MMBtu. Emission rates shown in Table 5-11 represent average emission rates that the control options would be expected to achieve during normal operations.

Table 5-11. Evaluate Technically Feasible NO_x Control Options for Effectiveness

Control Technology	NO _x Emission Rate ^(Note 1) lb/MMBtu	% Reduction from Baseline Emission Rate
Baseline (existing SOFA)	0.46	-
SCR – Tail-End Configuration ^(Note 2)	0.09	80.3%
SNCR + RRI + Combustion Optimization	0.20	56.2%
SNCR + Combustion Optimization	0.28	38.7%
Combustion Optimization	0.42	8.0%

Note 1. Emission rates shown in Table 5-11 represent average emission rates that the control options would be expected to achieve on an on-going long-term basis under normal operating conditions for Coyote Unit 1. Emission rates are provided for comparative purposes, and should not be construed to represent proposed emission limits. Corresponding permit limits must be evaluated on a control system-specific basis; an additional margin would likely be needed to account for operating margin. Additionally, for control options that include SNCR or RRI, computational fluid dynamic modeling and temperature mapping of the boiler would be needed to confirm that the incremental reduction in NO_x emission is achievable without creating unacceptable operational issues.

Note 2. Tail-end SCR has not been installed on a North Dakota lignite-fired unit, and extended trials would be needed to better understand the design and operation of tail-end SCR on Coyote Unit 1. Nevertheless, during the initial planning period, tail-end SCR was included in the reasonable progress analysis for Coyote Unit 1, and evaluated the costs and cost-effectiveness of the control system. For consistency with the first planning period, tail-end SCR will be carried forward to the Four Factor Analysis.

6. COSTS OF COMPLIANCE (STATUTORY FACTOR ONE)

The economic analysis performed as part of the Four Factor analysis examines the cost-effectiveness of each technically feasible control technology, on a dollar per ton of pollutant removed basis. Annual emissions, calculated for a particular control device, are subtracted from baseline annual emissions to calculate tons of pollutant controlled per year. For units with existing controls, the base case represents existing baseline actual emissions. Annual costs for each control option are calculated relative to the base case by adding annual operation and maintenance (O&M) costs to the annualized cost of capital and, if applicable, lost revenue due to extended outage required for installation of control equipment. Capital costs and lost revenues were annualized using a capital recovery factor based on an annual interest rate of 5.25%⁴⁰ and equipment life of 20 years.⁴¹ Cost effectiveness (\$/ton) of a particular control option is simply the annual cost (\$/yr) divided by the annual reduction in annual emissions (ton/yr). In addition to cost-effectiveness relative to the base case, the incremental cost-effectiveness to go from one level of control to the next, more stringent, level of control may also be calculated to evaluate the incremental cost effectiveness of the more stringent control.

Capital and O&M cost estimates were developed for each of the technically feasible SO₂ and NO_x control options. The Coyote Unit 1 cost estimates are conceptual in nature; thus, S&L did not procure equipment quotes specifically for the Unit 1 control system upgrades. Rather, equipment costs are based on conceptual designs developed for the retrofit control systems, preliminary equipment sizing developed for the major pieces of equipment (based on Coyote Unit 1-specific design parameters, including typical fuel characteristics, full load heat input, and flue gas temperatures and flow rates), and recent pricing for similar equipment. S&L would characterize the cost estimates for the Coyote Unit 1 retrofit technologies as “concept screening” cost estimates generally based on parametric models, judgment, or analogy.

⁴⁰ In an email to the North Dakota Department of Health dated December 18, 2018, EPA recommended use of a 5.25% interest rate. Otter Tail does not necessarily agree that this is an appropriate percentage to use and reserves the right to update and modify this percentage at a later date. Notably, on September 26, 2018 the North Dakota Public Service Commission approved a rate of return for Otter Tail of 7.64% (See <https://psc.nd.gov/database/documents/17-0398/226-020.pdf>). This ROR represents a total weighted average cost of capital. An interest rate of 5.25% is more representative of the long-term cost of debt, which is only one component of capital structure.

⁴¹ The assumed 20-year equipment life is consistent with the control system equipment life used by NDDH in its evaluation of NO_x and SO₂ control technologies for BART-eligible sources. (see, e.g., ND Regional Haze Final SIP, Appendix C.1, “BART Determination Study for Leland Olds Station Units 1 & 2, Basin Electric Power Cooperative, August 2006, pgs. 64 (NO_x controls) and 158 (SO₂ controls). See also, ND Regional Haze Final SIP, Appendix C4, “NO_x Best Available Control Technology Study for Milton R. Young Station Unit 1, Minnkota Power Cooperative, Inc., October 2006, pg. 3-22).

Control technology equipment costs for the retrofit options were developed by scaling cost estimates prepared by S&L for other similar projects. Major equipment costs were developed based on equipment costs recently developed for similar projects, and include the equipment, material, labor, and all other direct costs needed to retrofit the units with the control technology. Sub-accounts for the capital cost estimates (e.g., mobilization and demobilization, consumables, Contractor G&A expense, freight on materials, etc.) were developed by applying ratios from detailed cost estimates that were prepared for projects with similar scopes.

Fixed O&M costs include operating labor, maintenance labor, maintenance material, and administrative labor. Variable O&M costs include the cost of consumables, including reagent, water consumption, and auxiliary power requirements.⁴² Auxiliary power requirements reflect the additional power requirements associated with the operation of the new control technology (compared to the existing technology). All O&M costs reflect the incremental increase in O&M costs compared to the costs incurred to operate the existing dry scrubber and FF control systems.

In addition to the cost effectiveness relative to the base case, the incremental cost-effectiveness to go from one level of control to the next more stringent level of control will also be calculated to evaluate the cost effectiveness of the more stringent control.

The results of the SO₂ and NO_x control cost evaluations are included below in Sections 6.1 and 6.2.

6.1 ECONOMIC EVALUATION – SO₂ CONTROLS

Table 6-1 presents the capital costs and annual operating costs associated with installing and operating each technically feasible SO₂ control system for Unit 1. Table 6-2 shows the average annual and incremental cost effectiveness for each control system. Additional cost details are provided in Appendix B.

Cost estimates were not prepared for the SDA/FF option since the capital and operating costs for the SDA/FF option would be similar to the costs for the CDS/FF option, and the CDS/FF option would likely provide the opportunity to achieve somewhat lower controlled SO₂ emissions (compared to SDA/FF). Therefore, of the two new DFGD system options, only the CDS/FF option was evaluated.

⁴² Variable O&M costs are based on the annual average uncontrolled SO₂ of 2.77 lb/MMBtu

Table 6-1. SO₂ Control Cost Summary (\$2018)

SO ₂ Control Option	Total Capital Investment \$	Annualized Capital Cost \$/yr	Annual Operating Cost \$/yr	Total Annual Cost \$/yr
DSI + Existing FGD	\$23,765,000	\$1,948,000	\$12,329,000	\$14,277,000
FGD Operational Improvements – Increase Ca:S Stoichiometric Ratio	\$526,000	\$43,000	\$2,449,000	\$2,492,000
DSI + FGD Operational Improvements	\$24,292,000	\$1,991,000	\$14,779,000	\$16,770,000
FGD Upgrades - Replacing Existing Absorbers with New Absorber	\$127,823,000	\$10,475,000	\$6,332,000	\$22,197,000 ^(Note 1)
Dry FGD (CDS) + Existing FF	\$242,647,000	\$19,885,000	\$22,361,000	\$42,246,000
Wet FGD	\$324,742,000	\$26,613,000	\$23,001,000	\$49,614,000

Note 1. Total annual cost for “FGD Upgrades - Replacing Existing Absorbers with New Absorber” option includes annualized lost revenue due to extended outage and replacement power required for installation (\$5,390,000).

Table 6-2. SO₂ Emissions Control System Cost Effectiveness (\$2018)

SO ₂ Control Option	Total Annual Cost \$/yr	Expected Emission Reduction tons SO ₂ /yr	Average Annual Cost Effectiveness (Note 1) \$/ton SO ₂ removed	Incremental Annual Cost Effectiveness (Note 2, 3) \$/ton SO ₂ removed
Baseline (Existing DFGD/FF)	---	---	---	---
DSI + Existing FGD	\$14,277,000	4,131	\$3,456	
FGD Operational Improvements – Increase Ca:S Stoichiometric Ratio	\$2,492,000	5,354	\$465	n/a
DSI + FGD Operational Improvements	\$16,770,000	7,952	\$2,109	\$5,496
FGD Upgrades - Replacing Existing Absorbers with New Absorber	\$22,197,000	8,563	\$2,592	\$8,879
Dry FGD (CDS) + Existing FF	\$42,246,000	11,619	\$3,636	\$6,560
Wet FGD	\$49,614,000	12,078	\$4,108	\$16,072

Note 1. Average cost effectiveness for each control option is the total annual cost divided by the expected emission reduction.

Note 2. Incremental cost effectiveness represents the incremental increase in annual costs (\$/yr) divided by the incremental increase in annual emissions reductions (tpy) between a control option and the next most effective option.

Note 3. “n/a” indicates that the next most effective control option is “inferior” (i.e., higher cost for less control)

Table 6-2 indicates that the average annual cost effectiveness of the technically feasible SO₂ control options for Unit 1 range from \$465 per ton (FGD Operation Improvements) to \$4,108 per ton (Wet FGD). Costs associated with equipment procurement and installation, and annual operating costs all have a significant impact on the cost of the SO₂ control systems.

Annual costs of the DSI system exceed the costs of the FGD Operational Improvements option, and the DSI system achieves lower SO₂ reductions. Therefore, the DSI system is an “inferior” control option.

The FGD Operational Improvements option would require the relatively low capital investment for upgrading the existing atomizer wheel and an increase in operating costs primarily due to increased reagent usage. This option will achieve approximately 41% SO₂ reduction from the baseline levels, resulting in a cost effectiveness of \$465 per ton.

The option to incorporate FGD Operational Improvements and install a DSI system will achieve approximately 61% SO₂ reduction from the baseline. Capital costs are primarily attributed to the DSI equipment, and high operating costs are due to a significant increase in hydrated lime use. The cost effectiveness of the DSI + FGD Operational Improvements option is \$2,109 per ton. Comparing this option to the next most effective control option, FGD Operational Improvements (without DSI), the incremental costs effectiveness is \$5,496 per ton.

Replacing the existing absorber modules with new absorber modules will require Coyote Unit 1 to be taken off-line for approximately 12 months. In addition to capital and operating costs, the Coyote Station will incur costs associated with lost production and purchase of replacement power. The cost effectiveness of the FGD Upgrade - Replacing Existing Absorbers with New Absorber option is \$2,592 per ton. Comparing this option to the next most effective control option, DSI + FGD Operational Improvements, the incremental cost effectiveness is \$8,879 per ton.

The installation of new Dry FGD (CDS) or new Wet FGD systems are high capital and annual operating cost options. The cost effectiveness for these options are \$3,636 per ton (Dry FGD) and \$4,108 per ton (Wet FGD). The incremental cost of installing a Dry FGD system, compared to FGD Upgrades, is \$6,560 per ton. The incremental cost of installing a Wet FGD system, compared to a Dry FGD system, is \$16,072 per ton.

6.2 ECONOMIC EVALUATION – NO_x CONTROLS

Table 6-3 presents the capital costs and annual operating costs associated with building and operating each control system. Table 6-4 shows the average annual and incremental cost effectiveness for each control system. Additional cost details are provided in Appendix C.

Table 6-3. NO_x Control Cost Summary (\$2018)

NO _x Control Option	Total Capital Investment \$	Annual Capital Cost \$/yr	Annual Operating Cost \$/yr	Total Annual Cost \$/yr
Combustion Optimization	\$0	\$0	\$0	\$0
SNCR + Combustion Optimization	\$19,840,000	\$1,626,000	\$3,128,000	\$4,754,000
SNCR + RRI + Combustion Optimization	\$25,895,000	\$2,122,000	\$6,495,000	\$8,617,000
SCR – Tail-End Configuration	\$254,128,160	\$20,826,000	\$20,442,000	\$41,268,000

Table 6-4. NO_x Emissions Control System Cost Effectiveness (\$2018)

NO _x Control Option	Total Annual Cost \$/yr	Expected Emission Reduction tons NO _x /yr	Average Annual Cost Effectiveness (Note 1) \$/ton NO _x removed	Incremental Annual Cost Effectiveness (Note 2) \$/ton NO _x removed
Baseline (Existing SOFA)	---	---	---	---
Combustion Optimization	\$0	589	\$0	\$0
SNCR + Combustion Optimization	\$4,754,000	2,847	\$1,670	\$2,105
SNCR + RRI + Combustion Optimization	\$8,617,000	4,137	\$2,083	\$2,994
SCR – Tail-End Configuration	\$41,268,000	5,912	\$6,981	\$18,402

Note 1. Average cost effectiveness for each control option is the total annual cost divided by the expected emission reduction.

Note 2. Incremental cost effectiveness represents the incremental increase in annual costs (\$/yr) divided by the incremental increase in annual emissions reductions (tpy) between a control option and the next most effective option.

Table 6-4 indicates that the average annual cost effectiveness of the technically feasible NO_x control options for Unit 1 range from \$0 per ton (Combustion Optimization) to \$6,981 per ton (TE-SCR) NO_x removed.

The Combustion Optimization option is expected to achieve 8% NO_x reduction from baseline levels without impact to boiler performance. This option can be implemented without additional capital or operating costs; therefore, the cost effectiveness is \$0 per ton.

Installation of an SNCR system is expected to achieve approximately 39% NO_x reduction. The cost effectiveness of this option is \$1,670 per ton. Compared the next most effective option, Combustion Optimization, the incremental cost effectiveness is \$2,105 per ton.

The option to install an SNCR system combined with RRI would achieve approximately 56% NO_x reduction. Compared to installing SNCR alone, this option incurs additional capital costs for the RRI system and higher operating costs primarily due to increased urea consumption. The cost effectiveness of the SNCR + RRI option is \$2,083 per ton, and the incremental cost compared to SNCR alone is \$2,994 per ton.

Tail-end SCR system costs have been included to remain consistent with the reasonable progress analysis for Coyote Unit 1 during the initial planning period (i.e., evaluating the control system for costs and cost effectiveness). Based on preliminary cost estimates, the cost effectiveness of a tail-end SCR system is \$6,981 per ton. Compared to the next most effective control option, SNCR + RRI, the incremental cost effectiveness is \$18,402 per ton.

7. TIME NECESSARY FOR COMPLIANCE (STATUTORY FACTOR TWO)

The time necessary for compliance is generally defined as the time needed for full implementation of the technically feasible control options. This includes the time needed to develop and implement the regulations, as well as the time needed to install the selected control equipment. The time needed to install the control equipment includes time for equipment procurement, design, fabrication, and installation. If reasonable progress measures are required at Coyote Station for the Regional Haze second planning period, the anticipated compliance deadline would be July 1, 2028.⁴³ However, this compliance deadline must provide a reasonable amount of time for the source to implement the control measure.

Table 7-1 and Table 7-2 include estimated timeframes needed to implement each of the technically feasible control options. Notably, the estimated timeframes do not account for time needed for North Dakota to develop and implement the regulations; nor the amount of time needed for EPA to take proposed and final action to approve North Dakota's SIP.

⁴³ For the first planning period, on March 14, 2011 the North Dakota Department of Health issued permit to construct number PTC10008 that required Coyote Station to meet the approved reasonable progress limitation by July 1, 2018.

Table 7-1. SO₂ Emissions Control System Implementation Schedule

SO ₂ Control Option	Design / Specification / Procurement (months)	Detail Design / Fabrication (months)	Construction / Commissioning / Startup (months)	Total (months after SIP approval)
DSI + Existing FGD	6	6	6	18
FGD Operational Improvements – Increase Ca:S Stoichiometric Ratio	0	0	0	0
DSI + FGD Operational Improvements	6	6	6	18
FGD Upgrades - Replacing Existing Absorbers with New Absorber	8	12	12	32
Dry FGD (CDS) + Existing FF	12	20	18	50
Wet FGD	12	22	22	56

Table 7-2. NO_x Emissions Control System Implementation Schedule

NO _x Control Option	Design / Specification / Procurement (months)	Detail Design / Fabrication (months)	Construction / Commissioning / Startup (months)	Total (months after SIP approval)
Combustion Optimization	0	0	0	0
SNCR + Combustion Optimization	10	6	6	22
SNCR + RRI + Combustion Optimization	10	6	6	22
SCR – Tail-End Configuration	10	18	24	52

8. ENERGY AND NON-AIR QUALITY ENVIRONMENTAL IMPACTS (STATUTORY FACTOR THREE)

The primary purpose of the environmental impact analysis is to assess collateral environmental impacts due to control of the regulated pollutant in question. Environmental impacts may include solid or hazardous waste generation, discharges of polluted water from a control device, visibility impacts, increased emissions of other criteria or non-criteria pollutants, increased water consumption, and land use impacts from waste disposal.

8.1 ENVIRONMENTAL IMPACTS

Coyote Unit 1 is currently equipped with SOFA for NO_x control and dry scrubber technology for SO₂ control. The hydrated lime reactant used in a dry scrubbing system reacts with SO₂ in the flue gas to form calcium sulfate and calcium sulfite solids. The solids are captured in the existing FF particulate control system and either returned to the system for reuse or removed from the system as nonhazardous solid waste. The existing dry scrubbing system also requires water to hydrate the lime prior to injection into the reaction modules. Based on the design of the control system, Coyote Unit 1 currently uses approximately 465 gpm of water to hydrate the lime (at full load). Collateral environmental impacts associated with the existing Coyote Unit 1 control systems include water consumption and increased solid waste generation. There were no collateral impacts associated with the SOFA system.

Based on a review of potential non-air quality environmental impacts, no significant collateral environmental impacts were identified for any of the SO₂ and NO_x control options included in this evaluation, with the exception, potentially, of the WFGD, DSI, TE-SCR and SNCR/RRI options. No significant non-air quality environmental impacts were identified for the options that include replacing the existing scrubber modules with new scrubber modules, FGD operational improvements/upgrades or combustion optimization. Collateral environmental impact identified for the sorbent injection control option includes an increase in the solid waste generation. The sorbent injection system will increase the solid waste generated by approximately 50% (47,000 lb/hr to 70,000 lb/hr).

There are a number of potential non-air quality environmental impacts associated with the WFGD control option. Unlike dry scrubbing systems that generate a dry FGD byproduct, WFGD systems generate a liquid calcium sulfate by-product that must be dewatered prior to disposal. WFGD control systems can be designed with forced oxidation that results in a gypsum-grade by-product that can be sold into the local gypsum market. If an adequate gypsum

market is not available, the gypsum by-product will require disposal. WFGD control systems also generate a wastewater stream that must be treated prior to discharge. WFGD wastewaters typically consist of a saturated solution of calcium sulfate, calcium sulfite, and sodium chloride, with trace amounts of fly ash and unreacted limestone. Traces of metal ions may also be present due to fly ash carryover from the flue gas to the WFGD scrubber liquor. WFGD wastewater treatment systems typically require calcium sulfate/sulfite desaturation, heavy metals precipitation, coagulation/precipitation, and sludge dewatering. Treated wastewater is typically discharged to surface water pursuant to an NPDES discharge permit, and solids are typically disposed of in a landfill.

WFGD systems also require significantly more water than the dry systems. Based on design criteria for wet and dry FGD control systems, WFGD systems typically require approximately 25-30% more water than a similarly sized DFGD control system. This would increase water consumption at Coyote Unit 1 on average approximately 130 gpm. Water consumption is an important factor when assessing potential non-air quality environmental impacts at facilities located in North Dakota, and could represent a significant non-air quality collateral environmental impact.

In addition, the TE-SCR, SNCR and SNCR/RRI control options have a number of collateral impacts. The TE-SCR catalyst oxidizes some of the SO_2 to SO_3 in addition to catalyzing the reaction between NO_x and ammonia. There could be the potential for increased SO_3 emissions with the use of a TE-SCR. The SO_3 will react with the moisture in the stack to form H_2SO_4 emissions. In addition both the TE-SCR and SNCR, SNCR/RRI options utilize ammonia as the reagent for the reactions with NO_x to occur. There will be some ammonia slip emission from a TE-SCR in the range of 2 ppm. However the ammonia slip emission from a SCR or SNCR/RRI control technology will be significantly higher at 10 ppm. Ammonia slip emissions from the SNCR/RRI options will likely end up in the dry FGD solids, however there is no means to capture the ammonia slip emissions from the TE-SCR since it is installed prior to the stack.

8.2 ENERGY IMPACTS

Options that include replacing the existing Unit 1 dry scrubbing system with a CDS/FF or WFGD system or adding a TE-SCR will increase pressure drop through the control systems, increase auxiliary power requirements, and adversely affect the unit's net plant heat rate (Btu heat input per MW_{Net} output).⁴⁴ Consequently, heat input to the

⁴⁴ Heat rate represents the amount of heat input to the boiler (Btu) required to generate one megawatt (MW) net electric output and is reported as $\text{Btu}/\text{MW}_{\text{Net}}$.

boiler would need to increase to compensate for the increased auxiliary power requirements while achieving the same net plant output, or net output from the unit would decrease.

Although several of the control options have energy impacts, none of the impacts are considered significant enough as to disqualify any of the options from consideration in the four factor analysis. In order to account for potential energy impacts associated with each option, the auxiliary power cost associated with operating the control systems have been included as an annual operating cost in the economic impact assessment.

8.3 ENVIRONMENTAL / ENERGY IMPACTS SUMMARY

A summary of the environmental and energy impact analysis is provided in Table 8-1.

Table 8-1. Summary of Energy and Non-Air Quality Environmental Impacts

Control Option	Collateral Environmental & Energy Impacts
Baseline	<ul style="list-style-type: none"> ➤ Coyote Unit 1 is currently equipped with dry scrubbing / FF control systems. Existing collateral environmental and energy impacts include: ➤ Solid FGD by-product management and disposal ➤ Increased water consumption ➤ Increased auxiliary power requirements and heat rate penalty
SO₂ Control Options	
Replace existing DFGD with New WFGD control system	<ul style="list-style-type: none"> ➤ Increased water consumption ➤ Wet by-product that requires dewatering prior to disposal ➤ FGD wastewater treatment & discharge ➤ Increased auxiliary power requirements and heat rate penalty
Replace existing DFGD with New CDS/FF Control System	<ul style="list-style-type: none"> ➤ Increased auxiliary power requirements and heat rate penalty ➤ Increased solid FGD by-product management and disposal
Replace existing dry scrubber modules with New DFGD modules while keeping existing FF	<ul style="list-style-type: none"> ➤ Requires extended (approximately 12-month) outage of Coyote Unit 1 to demolish and replace the existing scrubber modules
Dry Sorbent Injection	<ul style="list-style-type: none"> ➤ Increased solid FGD by-product management and disposal ➤ Increased auxiliary power requirements and heat rate penalty
NO_x Control Options	
Selective Catalytic Reduction (SCR) - Tail End Configuration	<ul style="list-style-type: none"> ➤ Increased auxiliary power requirements and heat rate penalty ➤ Increased ammonia slip emissions ➤ Potential increase in SO₃ emissions
SNCR or SNCR + RRI	<ul style="list-style-type: none"> ➤ Increased ammonia slip emissions ➤ Increased auxiliary power requirements and heat rate penalty

9. REMAINING USEFUL LIFE (STATUTORY FACTOR FOUR)

The evaluation of technically feasible NO_x and SO₂ controls options should consider the source's "remaining useful life" in determining the costs of compliance. The remaining useful life is the difference between the date that controls would be put in place and the date that the facility permanently ceases operation. If the remaining useful life of the unit is shorter than the useful life of a particular control option, the remaining useful life should be used to annualize costs. If the remaining useful life exceeds the useful life of the control options, the remaining use life has no effect on the cost evaluation.

The cost of compliance for each control option (see Section 6) currently calculates the annual capital recovery cost by multiplying the total capital investment by a CRF from a formula based on a 20-year equipment lifetime. The Coyote Station owners have not identified dates for the remaining useful life of the unit before the end of what would otherwise be the useful life of the control measures that were evaluated for Coyote Unit 1. Thus, the 20-year equipment life of the control measures was used in the four factor analysis to calculate emission reductions, amortized costs, and cost-effectiveness.

10. FOUR-FACTOR ANALYSIS SUMMARY

At the request of NDDH, a four factor analysis was prepared for Coyote Unit 1. The analysis identified technically feasible SO₂ and NO_x control options for Unit 1, and evaluated each of the control measures for the following four statutory factors:

1. The costs of compliance;
2. The time necessary for compliance;
3. The energy and non-air quality environmental impacts of compliance; and
4. The remaining useful life of any potentially affected anthropogenic source of visibility impairment.

The cost of compliance evaluation prepared for SO₂ controls indicates that the average annual cost effectiveness ranges from \$465 per ton (FGD Operation Improvements) to \$4,108 per ton (Wet FGD). The evaluation prepared for NO_x controls options indicates that the average annual cost effectiveness ranges from \$0 per ton (Combustion Optimization) to \$6,981 per ton (TE-SCR) NO_x removed.

The time necessary for compliance for the SO₂ control options ranges from 0 months (FGD operational improvements) to 56 months (new wet FGD system). For NO_x control options, the time necessary for compliance ranges from 0 months (combustion optimization) to 46 months (tail-end SCR).

An evaluation of energy impacts indicates that certain control options (e.g., new FGD systems, TE-SCR) will increase auxiliary power requirements due to increased pressure drop, which would adversely impact net plant heat rate. Consequently, heat input to the boiler would need to increase to compensate for the increased auxiliary power requirements while achieving the same net plant output, or net output from the unit would decrease. Collateral environmental impacts include an increase in the solid waste generation with DSI, as well as potential incremental increase in fugitive dust emissions associated with sorbent deliveries to the facility.

Regarding remaining useful life, the Coyote Station owners have not identified dates for the remaining useful life of the unit before the end of what would otherwise be the 20-year useful life of the control measures that were evaluated for Coyote Unit 1. Therefore, the remaining useful life did not impact the annualized cost of control under the current regulatory framework.

Total Capital Investment (TCI)	\$254,128,000		sum of direct capital costs, indirect capital costs, and contingency
Capital Recovery Factor (CRF) = $i(1+i)^n / (1+i)^n - 1$	0.0820		20 year life of equipment (years) @ 5.25% interest.
Annualized Capital Costs (CRF x TCI)	\$20,826,000		
OPERATING COSTS			
Operating & Maintenance Costs			
Variable O&M Costs			
Dry Urea Reagent Cost	\$0		Based on dry urea reagent cost of \$354 per ton.
Ammonia Reagent Cost	\$1,724,000		Based on ammonia reagent cost of \$700 per ton.
RO Water Cost	\$0		Based on water cost of \$1.00 per 1,000 gallons.
Steam Cost	\$0		Based on steam cost of \$1.06 per MMBtu.
Hydrated Lime Cost	\$298,000		Based on hydrated lime cost of \$187 per ton.
Catalyst Replacement and Disposal Cost	\$4,257,000		Based on catalyst cost of \$8,000 per m3 and catalyst replacement cost of \$1,000 per m3.
Auxiliary Power Cost	\$1,074,000		Based on auxiliary power cost of \$23 per MWh
Total Variable O&M Costs	\$7,353,000		
Fixed O&M Costs			
Additional Operators per Shift	1		
Operating Labor	\$434,000		Assume \$49.5/hr for each additional operator
Supervisor Labor	\$65,000		
Maintenance Materials	\$2,425,000		15% of Operating Labor. EPA Cost Manual Section 1, Chapter 2, page 2-31. Includes costs for maintenance materials and maintenance labor. Based on 1.5% of Total Direct Costs
Maintenance Labor	\$0		Included in cost for maintenance materials.
Total Fixed O&M Cost	\$2,924,000		
Indirect Operating Cost			
Property Taxes	\$2,541,000		1% of TCI. EPA Cost Manual Section 1, Chapter 2, page 2-34.
Insurance	\$2,541,000		1% of TCI. EPA Cost Manual Section 1, Chapter 2, page 2-34.
Administration	\$5,083,000		2% of TCI. EPA Cost Manual Section 1, Chapter 2, page 2-34.
Total Indirect Operating Cost	\$10,165,000		
Total Annual Operating Cost	\$20,442,000		
TOTAL ANNUAL COST			
Annualized Capital Cost	\$20,826,000		
Annual Operating Cost	\$20,442,000		
Total Annual Cost	\$41,268,000		

May 10, 2019

Mr. Jim Semerad
Director, Division of Air Quality
North Dakota Department of Environmental Quality
Gold Seal Center, 918 East Divide Ave
Bismarck, ND 58501-1947

Dear Mr. Semerad:

Re: Four Factor Analysis - Coyote Station

Thank you for the North Dakota Department of Environmental Quality's (NDDEQ) review of the Coyote Station Regional Haze reasonable progress report (Four-Factor Analysis). Below are Otter Tail Power Company's (OTP) responses to the NDDEQ's March 20, 2019 comments. Additionally, two hardcopies of a revised report are enclosed.

- 1) Summary of NDDEQ Comment: "...since you are anticipating a higher sulfur content in the future lignite combusted, past emissions do not represent a realistic estimate of anticipated emissions... The SO₂ analysis should be edited using a more appropriate baseline rate."

OTP Response: The NDDEQ is correct that, as compared to recent years, Coyote Station is expecting an increase in future coal sulfur content. However, this future sulfur content is projected to be similar to the sulfur content of the lignite that was combusted from the years 2000-2008. On March 29, 2019 OTP provided a spreadsheet to the NDDEQ showing that Coyote Station has been able to maintain consistent SO₂ lb/mmbtu emission rates throughout the expected range of future coal sulfur content. For example, in year 2004, the average lignite sulfur content was 1.09%, and Coyote had an annual average emission rate of 0.85 lb/mmbtu. This emission rate is very similar to year 2018, in which Coyote had an average sulfur content of 0.83% and an annual average emission rate of 0.86 lb/mmbtu. Therefore, no adjustment is needed to the SO₂ baseline emission rate presented in the Four-Factor Analysis.

- 2) NDDEQ Comment: "We also believe the inlet SO₂ rate to possible control options (3.12 lb/MBtu) is high. Using the AP-42 emission factor, we calculate an inlet emission rate of approximately 2.3 lb/MBtu for 1.06% sulfur in the lignite. We believe this will affect the Total Annual Cost and cost effectiveness of the various control options. The analysis should be changed based on a more realistic inlet SO₂ rate."

OTP Response: We appreciate the NDDEQ's comment regarding calculation of the baseline SO₂ inlet rate. Sargent & Lundy (S&L) used projected future fuel analyses (sulfur and higher heating value) provided by OTP to calculate the baseline inlet SO₂ rate, assuming 100% conversion of fuel sulfur to SO₂ and without taking into account any inherent SO₂ conversion/capture. As pointed out by the NDDEQ, using the uncontrolled emission rate

factor provided by AP-42¹ as the basis for inlet SO₂ would provide for a lower number of approximately 2.3 lb/MMBtu.

Regarding revising the cost estimate consistent with the recommendation for inlet SO₂, the majority of the capital costs are a function of the flue gas flow rate and not the fuel sulfur content. Therefore, changing the inlet rate to 2.3 lb/MMBtu would change the capital cost estimate slightly but not enough to affect the economic impact evaluation. The reagent prep and dewatering systems and byproduct handling systems are a very small portion of the overall cost of the retrofit FGD control system. For the DSI system, the main cost is attributable to the variable O&M cost of reagent which was based on 2.77 lb SO₂/MMBtu as stated in Footnote 42 of the Four-Factor Analysis. The inlet SO₂ rate primarily impacts the variable O&M costs of the SO₂ control alternatives. Variable O&M costs that are impacted include reagent consumption (i.e., lime and limestone) and the byproduct or waste disposal. The difference between 2.3 lb SO₂/MMBtu and 2.77 lb SO₂/MMBtu will not have a significant impact on the FGD cost-effectiveness analysis because variable O&M costs are relatively small in relation to the capital cost portion of the SO₂ control alternatives. Nevertheless, S&L has revised the variable O&M costs to reflect a baseline SO₂ inlet rate of 2.3 lb SO₂/MMBtu.

- 3) Summary of NDDEQ Comment: *"...high dust, low dust and tail-end SCR are not technically feasible for cyclone boilers combusting North Dakota lignite...Since tail-end SCR is not a technically feasible option, we suggest that it be removed from Tables 5-11, 6-3 and 6-4."*

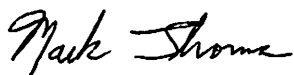

OTP Response: The Four-Factor Analysis has been revised to remove tail-end SCR from Tables 5-11, 6-3, and 6-4. Portions of the text were also updated to be consistent with this change.

- 4) NDDEQ Comment: *"Many cost estimates throughout the analysis are based on Sargent & Lundy's (S&L) conceptual cost estimating system with major equipment costs based on recently developed projects. When cost estimates are not based on EPA's Control Cost Manual, more documentation is required to substantiate costs. Please provide the documentation to support costs that are not based on the Control Cost Manual."*

OTP Response: Please see the attached memorandum from Sargent & Lundy addressing this comment.

Thank you for the attention given to the Coyote Station Four-Factor Analysis. If you have any further questions on the revised report, please contact me at (218) 739-8526.

Sincerely,

Mark Thoma
Manager, Environmental Services

Enclosure

¹ The AP-42 uncontrolled factor assumes that the alkali content of lignite has an effect on sulfur conversion and acts as a built-in sorbent for SO_x removal.

TECHNICAL MEMORANDUM

From: Wayshalee Patel
Date: May 8, 2019
Project No.: A12715.011

Client: Otter Tail Power
Station: Coyote Station

Subject: Agency Comments to Four Factor Analysis

The purpose of this memorandum is to provide a response to the North Dakota Department of Environmental Quality (NDDEQ) comments on the Coyote Station Four Factor Analysis.

- 1. NDDEQ Comment:** *Many cost estimates throughout the analysis are based on Sargent & Lundy's (S&L) conceptual cost estimating system with major equipment costs based on recently developed projects. When cost estimates are not based on EPA's Control Cost Manual, more documentation is required to substantiate costs. Please provide the documentation to support costs that are not based on the Control Cost Manual.*

S&L Response: S&L has considerable experience with the federal and state environmental regulations affecting power plant operations, as well as the specification, evaluation, selection, and implementation of emission control technologies for both gas- and coal-fueled utility power facilities, including extensive experience with air pollution control technologies. For example, since 2000, S&L has provided, or is currently providing, engineering services for the implementation of over 40 wet FGD projects, 30 dry FGD projects, 25 dry sorbent injection (DSI) projects, 60 selective catalytic reduction projects (SCR) and 30 selective non-catalytic reduction (SNCR) projects all of which are technologies that were analyzed as part of the Four-Factor Analysis.

Cost estimates for the OTP Four-Factor Analysis were, to the extent practical, prepared in accordance with the methodology described in EPA's Control Cost Manual and represent study-level cost estimates. Capital costs for major equipment were developed using equipment costs for similar sized units (adjusted for actual equipment sizing), an approach allowed by the Control Cost Manual. Site-specific balance-of-plant (BOP) costs that Coyote Unit 1 would incur to retrofit the control system onto the existing unit were estimated based on site-specific general arrangements and project-specific indirect cost factors. Where possible, default factors from EPA's Control Cost Manual were used to calculate indirect costs. Specifically, cost estimates were prepared with the following general approach and site-specific information:

- Boiler operating parameters were reviewed and mass balances were prepared to calculate flue gas flows across the range of operating conditions and to size the air pollution control equipment.
- Fuel characteristics were evaluated and used to size the material handling, material storage, and piping systems.
- Plant design data were used to estimate absorber sizing, reagent storage and preparation systems, dewatering systems and byproduct handling systems for air pollution control equipment.
- Aerial views of the plant were used to identify the general vicinity in which major equipment would be located.

The capital cost estimates were prepared for the major control system components, equipment, material, labor, instrumentation, etc. Capital costs were annualized using the methodology described in the Control Cost Manual, and annual operating and maintenance (O&M) costs were added to the annualized cost of capital to generate a total annual cost. Detailed cost effectiveness worksheets were provided identifying the O&M costs including, variable O&M costs (i.e. reagent, waste disposal, auxiliary power and water), indirect operating costs (i.e. property taxes, insurance, and administrative services) and fixed O&M costs (i.e. operating personnel as well as maintenance material and labor) for all of the air pollution control options. Where possible, default factors from EPA's Control Cost Manual were used to calculate O&M costs. The approach used by S&L to generate capital cost estimates, O&M costs, and total annual costs is in general accordance with the methodology outlined in the Control Cost Manual.

EXECUTIVE SUMMARY

Coyote Station, located near Beulah, ND, commenced commercial operation in 1981. The facility is a single unit station with one 451 MWg (approximate) Babcock and Wilcox cyclone boiler (Coyote Unit 1). Coyote Unit 1 is designed to fire North Dakota lignite, and is equipped with separated overfire air (SOFA) for NO_x control, and dry flue gas desulfurization (DFGD or dry FGD) and fabric filter baghouse (FF) for SO₂ and particulate matter (PM) control. Lignite is delivered to the Station from the Coyote Creek Mine, whose primary operations are approximately 3-4 miles from the Coyote Station.

On July 1, 1999, the U.S. Environmental Protection Agency (EPA) published regulations implementing Section 169A of the CAA, establishing a comprehensive visibility protection program for Federal Class I areas (the Regional Haze Rule).¹ The Regional Haze Rule requires each state to develop, and submit for approval by EPA, a state implementation plan (SIP) detailing the state's plan to protect visibility in Class I areas. The Regional Haze Rule established a schedule setting forth deadlines by which the States must submit their initial regional haze SIPs and subsequent revisions to the SIPs. Regional Haze SIPs for the initial planning period were due in 2007, with subsequent SIP updates due in 2018 and every 10 years thereafter.² Second planning period Regional Haze SIPs must be submitted to EPA for review by July 31, 2021.

As part of North Dakota's SIP development for the second planning period, NDDEQ requested that Otter Tail prepare a "four factor" analysis for Coyote Unit 1. This evaluation reviews technically feasible SO₂ and NO_x emissions reduction measures for the following four statutory factors:

1. The costs of compliance;
2. The time necessary for compliance;
3. The energy and non-air quality environmental impacts of compliance; and
4. The remaining useful life of any potentially affected anthropogenic source of visibility impairment.

Technically feasible SO₂ and NO_x control strategies for Coyote Unit 1 are included in Table ES-1 and Table ES-2. The tables also show baseline emission rates and estimated emission reductions for each control option.

¹ 64 FR 35713

² On January 10, 2017, EPA made a one-time adjustment to the due date for the second implementation period SIPs (2018 – 2028) by extending the deadline from July 31, 2018 to July 31, 2021 (82 FR 3078).

Table ES-1. SO₂ Control Options for Coyote Unit 1

Control Option	SO ₂ Emission Rate tons/yr	% Reduction from Baseline Emission Rate
Baseline (existing DFGD/FF)	12,994	-
DSI + Existing FGD	8,863	32%
FGD Operational Improvements – Increase Ca:S Stoichiometric Ratio	7,641	41%
DSI + FGD Operational Improvements	5,043	61%
FGD Upgrades - Replacing Existing Absorbers with New Absorber	4,432	66%
Dry FGD (CDS) + Existing FF	1,375	89%
Wet FGD	917	93%

Table ES-2. NO_x Control Options for Coyote Unit 1

Control Option	NO _x Emission Rate tons/yr	% Reduction from Baseline Emission Rate
Baseline (existing SOFA)	7,363	-
Combustion Optimization	6,775	8%
SNCR + Combustion Optimization	4,516	39%
SNCR + RRI + Combustion Optimization	3,226	56%

Costs of Compliance (Statutory Factor One)

Capital and O&M cost estimates were developed for each of the technically feasible SO₂ and NO_x control options. The Coyote Unit 1 cost estimates are conceptual in nature; thus, S&L did not procure equipment quotes specifically for the Unit 1 control system upgrades. Rather, equipment costs are based on conceptual designs developed for the retrofit control systems, preliminary equipment sizing developed for the major pieces of equipment (based on Coyote Unit 1-specific design parameters, including typical fuel characteristics, full load heat input, and flue gas temperatures and flow rates), and recent pricing for similar equipment.

Table ES-3 and Table ES-4 include estimated costs for SO₂ and NO_x control options for Coyote Unit 1. The tables provide the estimated annualized capital and operating and maintenance (O&M) costs, estimated emissions reductions, average annual cost effectiveness. The tables also include the incremental cost effectiveness that compares the costs and performance of a control option to those of the next most stringent option.

Table ES-3. SO₂ Emissions Control System Cost Effectiveness (\$2018)

SO ₂ Control Option	Total Annualized Cost \$/yr	Expected Emission Reduction tons SO ₂ /yr	Average Annual Cost Effectiveness (Note 1) \$/ton SO ₂ removed	Incremental Annual Cost Effectiveness (Note 2, 3) \$/ton SO ₂ removed
Baseline (Existing DFGD/FF)	---	---	---	---
DSI + Existing FGD	\$12,371,000	4,131	\$2,994	
FGD Operational Improvements – Increase Ca:S Stoichiometric Ratio	\$2,085,000	5,354	\$389	n/a
DSI + FGD Operational Improvements	\$14,456,000	7,952	\$1,818	\$4,762
FGD Upgrades - Replacing Existing Absorbers with New Absorber	\$22,197,000	8,563	\$2,592	\$12,664
Dry FGD (CDS) + Existing FF	\$40,495,000	11,619	\$3,485	\$5,987
Wet FGD	\$49,094,000	12,078	\$4,065	\$18,757

Note 1. Average cost effectiveness for each control option is the total annual cost divided by the expected emission reduction.

Note 2. Incremental cost effectiveness represents the incremental increase in annual costs (\$/yr) divided by the incremental increase in annual emissions reductions (tpy) between a control option and the next most effective option.

Note 3. "n/a" indicates that the next most effective control option is "inferior" (i.e., higher cost for less control)

Table ES-4. NO_x Emissions Control System Cost Effectiveness (\$2018)

NO _x Control Option	Total Annualized Cost \$/yr	Expected Emission Reduction tons NO _x /yr	Average Annual Cost Effectiveness (Note 1) \$/ton NO _x removed	Incremental Annual Cost Effectiveness (Note 2) \$/ton NO _x removed
Baseline (Existing SOFA)	---	---	---	---
Combustion Optimization	\$0	589	\$0	\$0
SNCR + Combustion Optimization	\$4,754,000	2,847	\$1,670	\$2,105
SNCR + RRI + Combustion Optimization	\$8,617,000	4,137	\$2,083	\$2,994

Note 1. Average cost effectiveness for each control option is the total annual cost divided by the expected emission reduction.

Note 2. Incremental cost effectiveness represents the incremental increase in annual costs (\$/yr) divided by the incremental increase in annual emissions reductions (tpy) between a control option and the next most effective option.

Time Necessary for Compliance (Statutory Factor Two)

Table ES-5 and Table ES-6 provide estimated timeframes needed to implement each of the technically feasible control option. Notably, the estimated timeframes do not account for time needed for North Dakota to develop and implement the regulations; nor the amount of time needed for EPA to take proposed and final action to approve North Dakota's SIP.

Table ES-5. SO₂ Emissions Control System Implementation Schedule

SO ₂ Control Option	Design / Specification / Procurement (months)	Detail Design / Fabrication (months)	Construction / Commissioning / Startup (months)	Total (months after SIP approval)
DSI + Existing FGD	6	6	6	18
FGD Operational Improvements – Increase Ca:S Stoichiometric Ratio	0	0	0	0
DSI + FGD Operational Improvements	6	6	6	18
FGD Upgrades - Replacing Existing Absorbers with New Absorber	8	12	12	32
Dry FGD (CDS) + Existing FF	12	20	18	50
Wet FGD	12	22	22	56

Table ES-6. NO_x Emissions Control System Implementation Schedule

NO _x Control Option	Design / Specification / Procurement (months)	Detail Design / Fabrication (months)	Construction / Commissioning / Startup (months)	Total (months after SIP approval)
Combustion Optimization	0	0	0	0
SNCR + Combustion Optimization	10	6	6	22
SNCR + RRI + Combustion Optimization	10	6	6	22

Energy and Non-Air Quality Environmental Impacts (Statutory Factor Three)

An evaluation of energy impacts indicates that certain control options (e.g., new FGD systems) will increase auxiliary power requirements due to increased pressure drop, which would adversely impact net plant heat rate. Consequently, heat input to the boiler would need to increase to compensate for the increased auxiliary power requirements while achieving the same net plant output, or net output from the unit would decrease. Collateral environmental impacts include an increase in the solid waste generation with DSI. A summary of the environmental and energy impact analysis is provided in Table ES-7.

Table ES-7. Summary of Energy and Non-Air Quality Environmental Impacts

Control Option	Collateral Environmental & Energy Impacts
<u>SO₂ Control Options</u>	
Replace existing DFGD with New WFGD control system	<ul style="list-style-type: none"> ➤ Increased water consumption ➤ Wet by-product that requires dewatering prior to disposal ➤ FGD wastewater treatment & discharge ➤ Increased auxiliary power requirements and heat rate penalty
Replace existing DFGD with New CDS/FF Control System	<ul style="list-style-type: none"> ➤ Increased auxiliary power requirements and heat rate penalty ➤ Increased solid FGD by-product management and disposal
Replace existing dry scrubber modules with New DFGD modules while keeping existing FF	<ul style="list-style-type: none"> ➤ Requires extended (approximately 12-month) outage of Coyote Unit 1 to demolish and replace the existing scrubber modules
Dry Sorbent Injection	<ul style="list-style-type: none"> ➤ Increased solid FGD by-product management and disposal ➤ Increased auxiliary power requirements and heat rate penalty
<u>NO_x Control Options</u>	
SNCR or SNCR + RRI	<ul style="list-style-type: none"> ➤ Increased ammonia slip emissions ➤ Increased auxiliary power requirements and heat rate penalty

Remaining Useful Life (Statutory Factor Four)

The Coyote Station owners have not identified dates for the remaining useful life of the unit before the end of what would otherwise be the useful life of the control measures that were evaluated for Coyote Unit 1. Thus, the 20-year

equipment life of the control measures was used in the four factor analysis to calculate emission reductions, amortized costs, and cost-effectiveness.

1. INTRODUCTION

Sargent & Lundy, L.L.C. (S&L) was retained by Otter Tail Power Company (Otter Tail) to prepare a Reasonable Progress four-factor analysis for the control of sulfur dioxide (SO₂) and nitrogen oxide (NO_x) emissions from Coyote Station Unit 1 (Coyote Unit 1).³ The evaluation is in response to North Dakota Department of Environmental Quality's (NDDEQ) request that Otter Tail prepare a four factor analysis for Coyote Unit 1.

The evaluation includes an assessment of potentially available emission reduction measures for the four statutory factors listed in 40 CFR 51.308(f)(2), and takes into consideration U.S. Environmental Protection Agency's (EPA's) *Draft Guidance on Progress Tracking Metrics, Long Term Strategies, Reasonable Progress Goals and Other Requirements for Regional Haze State Implementation Plans for the Second Implementation Period* (the "Draft EPA Guidance").⁴ Technically feasible SO₂ and NO_x emission reduction measures are evaluated for the following four statutory factors:

- Factor 1: The cost of compliance
- Factor 2: The time necessary to achieve compliances
- Factor 3: The energy and non-air quality environmental impact of compliance
- Factor 4: The remaining useful life of any existing source subject to such requirements

The Reasonable Progress four factor analysis for Coyote Unit 1 (the "Four Factor Analysis") is presented in the following sections:

- Section 2: Facility Description** contains information describing the facility, site location, and existing equipment.
- Section 3: Four-Factor Analysis Requirements** provides a brief description of the Regional Haze Program requirements set forth in 40 CFR 51.308.
- Section 4: Baseline SO₂ and NO_x Emissions** establishes representative baseline SO₂ and NO_x emissions for the period 2013 to present.

³ Coyote Station is co-owned by Otter Tail Power Company (35%), Northern Municipal Power Agency (30%), Montana-Dakota Utilities Co. (25%), and NorthWestern Energy (10%).

⁴ On September 11, 2018, EPA released a "Regional Haze Reform Roadmap" announcing its plan to "release a series of implementation tools and guidance documents that will help focus states' efforts and reduce and streamline the time and resources needed to meet the statutory and regulatory requirements for reducing regional haze in National Parks, wildlife refuges, and wilderness areas." EPA stated that it plans to issue a new guidance document on Regional Haze SIP Development by Spring, 2019. Otter Tail Power reserves the right to update and modify this four-factor analysis, as needed, to be consistent with any new guidance issued by the agency.

2. FACILITY DESCRIPTION

Coyote Station, located near Beulah, ND, commenced commercial operation in 1981. The facility is a single unit station with one 451 MWg (approximate) Babcock and Wilcox cyclone boiler (Coyote Unit 1). Coyote Unit 1 is designed to fire North Dakota lignite, and is equipped with separated overfire air (SOFA) for NO_x control, and dry flue gas desulfurization (DFGD or dry FGD) and fabric filter baghouse (FF) for SO₂ and particulate matter (PM) control. Lignite is delivered to the Station from the Coyote Creek Mine, whose primary operations are approximately 3-4 miles from the Coyote Station.

Table 2-1 provides a summary of the process parameters used for the Coyote Unit 1 Four Factor Analysis. Process parameters listed in Table 2-1 were developed from information provided by OTP.⁵

Table 2-1. Process Parameters

Process Parameter	Coyote Unit 1
Boiler Type	Cyclone
Boiler Manufacturer	B&W
Full Load (MWg)	451
Full Load Boiler Heat Input (MMBtu/hr)	4,900
Full Load Coal Flow (lb/hr)	700,700
Boiler Excess Air (%)	14.0
Air Heater Leakage (%)	22.0
Bottom Ash/Fly Ash Ratio	65/35
Flue Gas Conditions at Air Heater Outlet	
Temperature (F)	330
Mass Flow Rate (lb/hr)	6,532,000
Volumetric Flow rate (acfm)	2,485,000
Annual Average Fuel Sulfur Content (%)	0.82 - 1.06
Annual Average Uncontrolled SO ₂ Emissions ⁶ (lb/MMBtu)	2.42 - 3.12

⁵ These process parameters are representative of typical average conditions. They should not be construed as maximum values or unit design values.

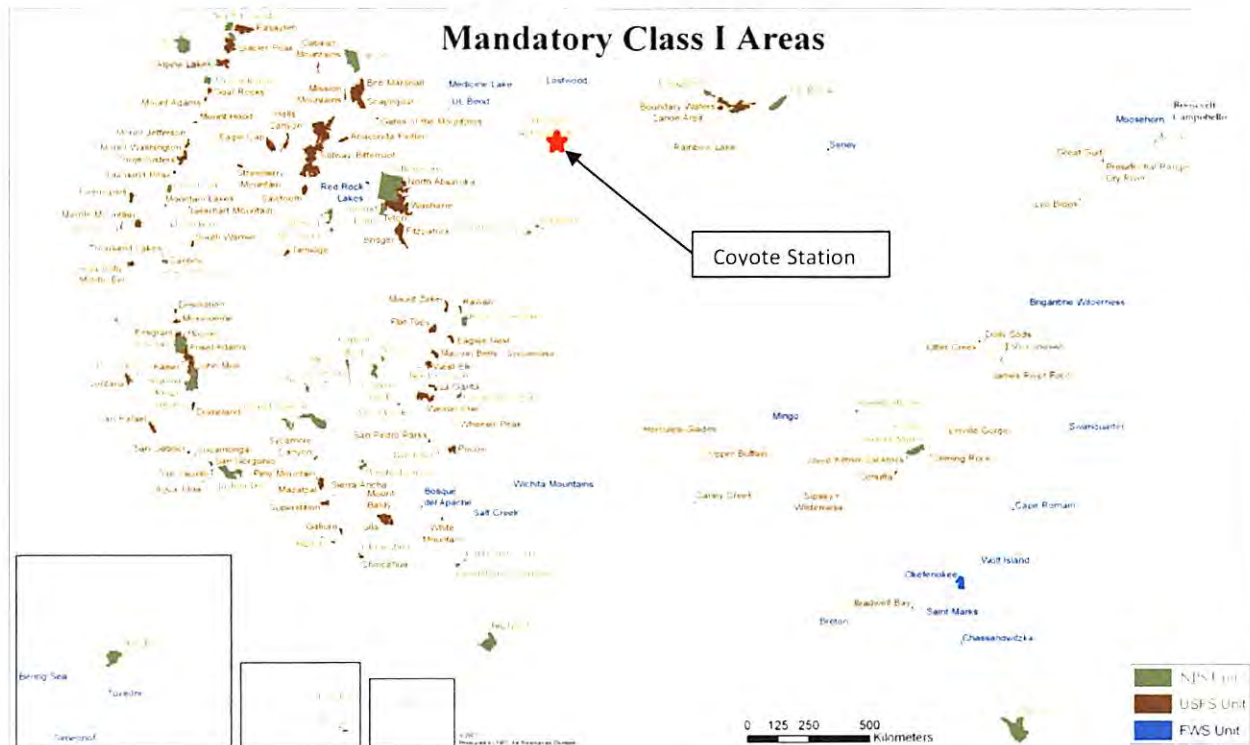

⁶ Assuming 100% conversion of fuel sulfur to SO₂.

3. FOUR-FACTOR ANALYSIS REQUIREMENTS

3.1 REGIONAL HAZE RULE BACKGROUND

Section 169A of the 1977 Amendments to the Clean Air Act (CAA) sets forth a program for protecting visibility in Federal Class I areas which calls for the “prevention of any future, and the remedying of any existing, impairment of visibility in mandatory Federal Class I areas which impairment results from manmade air pollution.” Federal Class I areas include national parks, memorial parks, and wilderness areas over a certain size. Figure 3-1 shows the locations of the 156 federally mandated Class I areas. Federal Class I areas located within North Dakota include the Theodore Roosevelt National Park and the Lostwood National Wildlife Refuge.

Figure 3-1. Federal Class I Areas

On July 1, 1999, the U.S. Environmental Protection Agency (EPA) published regulations implementing Section 169A of the CAA, establishing a comprehensive visibility protection program for Federal Class I areas (the Regional Haze Rule).⁷ The Regional Haze Rule requires each state to develop, and submit for approval by EPA, a

⁷ 64 FR 35713

state implementation plan (SIP) detailing the state's plan to protect visibility in Class I areas. In 2017, EPA issued a final rule revising portions of the 1999 Regional Haze Rule.⁸ The 2017 Rule requires states to determine the baseline (2000 - 2004) visibility condition for the 20 percent most impaired days and requires that the long-term strategy and reasonable progress goals (RPGs) must provide for improvement in visibility for the most impaired days, relative to the baseline period. Specifically, states must determine the rate of improvement in visibility that would need to be maintained during each implementation period in order to reach natural conditions by 2064 for the 20 percent most impaired days, given the starting point of the baseline visibility condition.

To address the combined visibility effects of various pollution sources over a wide geographic region, EPA designated five Regional Planning Organizations (RPOs) to assist with the coordination and cooperation needed to address the visibility issue. The five RPOs are shown in Figure 3-2. North Dakota is a member of the Western Regional Air Partnership (WRAP), which serves as the RPO for visibility protection at 118 Class I areas in the 15 western states.

Figure 3-2. Regional Planning Organization Map

⁸ Final Rule: Protection of Visibility: Amendments to Requirements for State Plans, 82 FR 3078, January 10, 2017

3.1.1 First Implementation Period

The Regional Haze Rule established a schedule setting forth deadlines by which the States must submit their initial regional haze SIPs and subsequent revisions to the SIPs. Regional Haze SIPs for the initial planning period were due in 2007, with subsequent SIP updates due in 2018 and every 10 years thereafter.⁹

Regional Haze SIP requirements for the first planning period required that states incorporate into their plans the core program requirements in 40 CFR 51.308(d), including: (1) establishing reasonable progress goals (RPGs) for each Class I area within the state that provide for measurable progress towards achieving natural visibility conditions; (2) developing a long-term strategy (LTS) including enforceable emissions limitations and compliance schedules to achieve the RPGs; and (3) developing plans to monitor and assess the effectiveness of the LTS to achieve the RPGs over the prior implementation period and affirmation of or revision to the RPGs.

The Regional Haze Rule requires that states determine the consistent rate of progress over time needed to attain natural visibility conditions on the 20 percent most anthropogenically impaired days by the year 2064. This “glidepath” is referred to as the uniform rate of progress (URP) line. States must consider the URP, and the emission reduction measures needed to achieve this level of improvement, when developing their RPGs and LTS. Regulations at 40 CFR 51.308(g) require each state to submit progress reports, in the form of SIP revisions, every 5 years following the submission of the initial SIP. These progress reports must evaluate the progress made towards the RPGs for Class I areas located within the state as well as those Class I areas located outside the state that may be affected by emissions from within the state.

3.1.1.1 Best Available Retrofit Technology

As a one-time requirement during the first implementation period, potential best available retrofit technology (BART) controls had to be evaluated for certain large stationary sources. States were required to conduct BART determinations for “BART-eligible” sources anticipated to cause or contribute to any visibility impairment in one or more Class I area. BART-eligible sources included coal-fired electric generating units (EGUs) that were in existence on August 7, 1977, but not in operation prior to August 7, 1962. In its determination of BART, states were required to take into consideration the costs of compliance, the energy and nonair quality environmental impacts of compliance, any existing pollution control technology in use at the source, the remaining useful life of

⁹ On January 10, 2017, EPA made a one-time adjustment to the due date for the second implementation period SIPs (2018 – 2028) by extending the deadline from July 31, 2018 to July 31, 2021 (82 FR 3078).

the source, and the degree of improvement in visibility which may reasonably be anticipated to result from the use of such technology.¹⁰ As an alternative to requiring source-specific BART controls, states also had the flexibility to adopt an emissions trading program or other alternative program as long as the alternative provided greater reasonable progress towards improving visibility than BART.

3.1.1.2 Reasonable Progress Control Requirements for Coyote Station during First Planning Period

Coyote Unit 1 commenced operation in 1981, and was not classified as a BART-eligible source or subject to the BART requirements. Nevertheless, during the initial planning period, the North Dakota Department of Environmental Quality (NDDEQ) evaluated emissions from the Coyote Station as a reasonable progress source. The reasonable progress analysis prepared by NDDEQ concluded that no additional controls would be required on Coyote Unit 1 during the initial planning period; however, NDDEQ and Otter Tail reached an agreement whereby Otter Tail committed to install SOFA equipment to reduce NO_x emissions. In the initial planning period SIP NDDEQ noted that additional SO₂ and NO_x controls for Coyote Unit 1 would be reevaluated during future planning periods to determine if additional emissions reductions would be required.

3.1.2 Second Implementation Period

Second planning period Regional Haze SIPs must be submitted to EPA for review by July 31, 2021. Among other requirements, second planning period SIPs are required to include an assessment of the state's RPGs and LTS. To support states in their efforts to develop the second planning period SIPs, in July 2016 EPA released a draft guidance document titled "*Draft Guidance on Progress Tracking Metrics, Long-term Strategies, Reasonable Progress Goals and Other Requirements for Regional Haze State Implementation Plans for the Second Implementation Period*" ("Draft EPA Guidance").¹¹ The Draft EPA Guidance document describes key steps states should implement when developing their RPGs and LTS for the second implementation period. Key steps identified in the Draft EPA Guidance are listed in Table 3-1.

¹⁰ CAA Section 169A(g)(2).

¹¹ See, EPA-457/P-16-001. On September 11, 2018, EPA released a "*Regional Haze Reform Roadmap*" announcing its plan to "release a series of implementation tools and guidance documents that will help focus states' efforts and reduce and streamline the time and resources needed to meet the statutory and regulatory requirements for reducing regional haze in National Parks, wildlife refuges, and wilderness areas." EPA stated that it plans to issue a new guidance document on Regional Haze SIP Development by Spring, 2019. Otter Tail Power reserves the right to update and modify this four-factor analysis, as needed, to be consistent with any new guidance issued by the agency.

Table 3-1. Key Steps in Developing Regional Haze SIPs for Second Planning Period

1. *Ambient data analysis* – Quantify baseline, current and natural conditions and the uniform rate of progress that would achieve natural conditions in 2064 (40 CFR 51.308(f)(1))
2. *Screening of sources* – Identify the pollutants and emission sources for which a full reasonable progress analysis will be completed and explain why it is appropriate to limit the full analysis to only these sources (40 CFR 51.308(f)(2))
3. *Source and emission control measure analysis* – Identify potential emission control measures for sources selected in the screening step and develop data on the four statutory factors and visibility benefits if they will be considered (40 CFR 51.308(f)(2))
4. *Decisions on the content of the LTS* – Consider applicable factors and decide on new emission controls for incorporation into the LTS (40 CFR 51.308(f)(2))
5. *Regional scale modeling* – Model the emissions reductions that will result from implementation of the LTS and other enforceable measures that will reduce visibility impairment to set the RPGs for 2028 (40 CFR 51.308(f)(3))
6. *Progress, degradation and glidepath checks* – Demonstrate that there will be an improvement on the 20 percent most impaired days. Demonstrate that there is no degradation on the 20 percent clearest days. Compare the 2028 RPG for the 20 percent most impaired days to the 2028 point on the URP line (the glidepath) and, if required, provide additional justification for the reasonableness of the RPG. Revise the LTS if additional measures are identified as necessary to make reasonable progress. (40 CFR 51.308(f)(3))
7. *Additional requirements for SIPs* – Provide additional information necessary to ensure that other requirements of the Regional Haze rule are met.

The Draft EPA Guidance recommends that states evaluate all technically feasible emission control options for stationary sources and source categories identified as having the greatest potential to impact visibility at one or more Class I area. The Draft EPA Guidance recommends several options for states to consider when evaluating potential emission reductions, including work practices, replacement and retrofit controls, existing control upgrades, fuel switching year-round operation of controls, and operating restrictions.¹²

Emission control evaluations must consider the four statutory factors identified in 40 CFR 51.308(f)(2)(i) (discussed in Section 3.2). In addition, the Draft EPA Guidance notes that control technology assessment recommendations presented in the BART Guidelines continue to be relevant as recommendations for how a state

¹² See, Draft EPA Guidance, pgs. 85-86.

should evaluate and select emission control measures for stationary sources.¹³ Recommendations in the BART Guidelines that continue to be relevant to the Regional Progress Four Factor Analysis are listed in Appendix D of the Draft EPA Guidance, and include, in general, the recommended approach for evaluating the technical feasibility, effectiveness, costs, and cost-effectiveness of available emission control measures.¹⁴

3.2 DESCRIPTIONS OF THE FOUR STATUTORY FACTORS

Under 40 CFR 51.308(f)(2)(i), states must consider four statutory factors when evaluating and determining emissions reduction measures from stationary sources, or groups of sources, that are necessary to make reasonable progress towards achieving natural visibility conditions. The four statutory factors are:

5. The costs of compliance;
6. The time necessary for compliance;
7. The energy and non-air quality environmental impacts of compliance; and
8. The remaining useful life of any potentially affected anthropogenic source of visibility impairment.

A brief description of each of the four statutory factors, and EPA's recommendations for evaluating each of the four factors (from the Draft EPA Guidance) is provided below.

3.2.1 Costs of Compliance

Cost estimates should be developed for each technically feasible control option. Costs include the total capital costs to engineer, design, procure, and install the control technology, and annual operating and maintenance (O&M) costs. O&M costs include both fixed and variable O&M. Fixed O&M includes costs that are independent of control system operation and would be incurred even if the control system were shut down. Fixed O&M includes categories such as operating and maintenance labor, administrative charges, property taxes, and insurance. Variable O&M includes the cost of consumables, including reagent (e.g., lime or limestone, ammonia, urea, etc.), by-product management, water consumption, and auxiliary power requirements associated with operating the control system. For existing facilities, O&M cost estimates should represent the control option's incremental increase over current O&M costs.

¹³ Draft EPA Guidance, pg. 85. The BART Guidelines are published at 40 CFR Part 51 Appendix Y.

¹⁴ Draft EPA Guidance, Appendix D, pgs. 186-196.

Capital costs include all costs required to engineer, design, procure, and install equipment needed for the control system. The Draft EPA Guideline recommends that states adhere to the accounting principles described in Chapter 2 Section 1 of EPA's Air Pollution Control Cost Manual (the "Control Cost Manual") when calculating control system costs for a four factor analysis.¹⁵

Section 2.3 of the Control Cost Manual (Section 1, Chapter 2) describes the cost categories generally used to calculate the total capital cost of a retrofit control technology. Cost categories include total capital investment (TCI), which is defined to "include all costs required to purchase equipment needed for the control systems (purchased equipment costs), the costs of labor and materials for installing that equipment (direct installation costs), costs for site preparation and buildings, and certain other costs (indirect installation costs). TCI also includes costs for land, working capital, and off-site facilities." Direct installation costs include costs for foundations and supports, erecting and handling the equipment, electrical work, piping, insulation, and painting. Indirect installation costs include costs such as engineering costs; construction and field expenses (i.e., cost for construction supervisory personnel, office personnel, rental of temporary offices, etc.); contractor fees (for construction and engineering firms involved in the project); start-up and performance test costs (to get the control system running and to verify that it meets performance guarantees); and contingencies.¹⁶

The total annual cost (TAC) of a control option includes the annualized capital recovery cost plus the total annual O&M costs. The Control Cost Manual recommends using an equivalent uniform annual cash flow method to annualize the total capital investment by multiplying the total capital investment by a capital recovery factor (CRF).¹⁷ The product of the total capital investment and CRF gives a uniform end-of-year payment necessary to repay the initial capital investment in "n" years at an interest rate of "i". The CRF is calculated using the following equation:

$$CRF = \frac{i * (1 + i)^n}{(1 + i)^n - 1}$$

Where:

i = interest rate; and

n = economic life of the emission control system

The Draft EPA Guidance suggests that states may use generic cost estimates or estimating algorithms for estimating

¹⁵ Draft EPA Guidance, pg.89.

¹⁶ EPA Air Pollution Control Cost Manual, Sixth Edition, EPA/452/B-02-001, January 2002, pg. 2-5.

¹⁷ Id., at pg 2-21.

control system costs; however, source specific estimates prepared by knowledgeable engineering professionals provide more reliable information than generic cost estimates.¹⁸ Source-specific cost estimate should be well documented for purposes of public comment and EPA review.¹⁹

The total annual cost of each control option (\$/yr) is divided by the total annual emissions reduction (tpy) to determine the control option's average cost-effectiveness on a \$/ton basis. Emissions reductions are calculated based on the difference between baseline annual emissions and post-control annual emissions. The Draft EPA Guidance generally recommends calculating baseline emissions based on projected 2028 emissions assuming source compliance with emission limits that have been adopted and are enforceable. As an alternative, baseline emissions may be based on representative past actual emissions, assuming there is no evident basis for using a different emissions rate.

3.2.2 Time Necessary for Compliance

For stationary sources, the provisions of the BART Guidelines regarding the time necessary for compliance are relevant to reasonable progress analyses. EPA recommends that prior experiences with the planning and installation of new emission controls is the best guide to how much time a particular source will reasonably need for compliance. However, source-specific factors should be considered when evaluating the time necessary to engineer, procure, and install an available and technically feasible control option. Source-specific factors that affect the time necessary to install new emission controls should be identified and documented in the four factor analysis.

3.2.3 Energy and Non-Air Quality Environmental Impacts

For stationary sources, the provisions of the BART Guidelines regarding energy impacts are relevant to reasonable progress analyses. Energy impacts of an emission control measure are a matter of engineering design and control system operation; thus, EPA recommends that prior experience at similar sources will be informative. Energy impacts may be considered in terms of kilowatt-hours or fuels used to operate the control system. The energy impact analysis should focus on direct energy consumption at the source rather than indirect energy inputs needed to produce raw materials for the construction and operation of control equipment.

¹⁸ Draft EPA Guidance, pg. 91.

¹⁹ Id.

For stationary sources, the provisions of the BART Guidelines regarding non-air quality environmental impacts are relevant to reasonable progress analyses. Non-air quality impacts include solid or hazardous waste generation, increased water consumption, wastewater discharge, land use impacts, and impacts to threatened and endangered species or their natural habitat. Characterizing the non-air quality environmental impacts should be done on a source-specific basis. Other guidance intended for use in assessments under the National Environmental Policy Act may be relevant to this evaluation.

Even though states are not required to consider GHG emission impacts, the Draft EPA Guidance encourages states to consider GHG impacts when developing their Long-Term Strategy.²⁰ As an example, some measures that would reduce emissions that contribute to visibility impairment will also reduce GHG emissions, such as measures that reduce the use of energy produced from combusting fossil fuels with relatively high GHG emissions. Conversely, control measures that require significant energy to capture visibility impairing emissions could result in increased GHG emission. Where a measure necessary to make reasonable progress towards natural visibility conditions would increase GHG emissions, Draft EPA Guidance encourages states to work to harmonize visibility and climate change objectives.²¹

3.2.4 Remaining Useful Life

For stationary sources, the provisions of the BART Guidelines regarding remaining useful life are relevant to reasonable progress analyses. In general, the remaining useful life of the source itself will be longer than the useful life of the emission control measure under consideration unless there is an enforceable requirement for the source to cease operation sooner. Thus, the useful life of the control measure will normally be used in the four factor analysis to calculate emission reductions, amortized costs, and cost-effectiveness. However, if there is an enforceable requirement for the source to cease operation by a date before the end of what would otherwise be the useful life of the control measure under consideration, then the enforceable shutdown date should be used to calculate remaining useful life and evaluate control technology cost-effectiveness.

²⁰ Draft EPA Guidance, pg. 92.

²¹ Id.

3.2.5 Four Factor Analysis Approach

S&L used the following approach to identify SO₂ and NO_x emission control options available to Coyote Unit 1 for inclusion in the Four Factor Analysis:

1. Establish representative baseline emissions achieved with existing controls.
2. Identify all potentially available control options.
3. Evaluate control options for technical feasibility (i.e., availability and applicability).
4. Eliminate control options that are not technically feasible or would have no practical application on Coyote Unit 1.
5. Determine the control effectiveness of each technically feasible control option.
6. Evaluate each technically feasible control option for the four statutory factors.

4. BASELINE SO₂ AND NO_x EMISSIONS

The first step in developing the Four Factor Analysis is to establish Coyote Unit 1 baseline SO₂ and NO_x emissions. To establish representative baseline emissions, S&L evaluated Coyote Unit 1 operating data for the period January 1, 2013 to June 30, 2018 to identify periods of normal operation (i.e., periods of operation when the boiler was not limited by infrequent or extraordinary operating restrictions). Based on review of fuels consumed, heat input to the boiler, boiler heat rates, power generation, and capacity factors, as well as input from OTP, it was determined that the operating periods of January 1, 2013 to December 31, 2014 and January 1, 2016 to June 30, 2018 were representative of normal operation. The year 2015 was not considered to be representative because Coyote Unit 1 was limited to approximately 50% load due to a boiler feed pump (BFP) overspeed event that damaged one of the unit's two 50% BFPs; thus, only one BFP was available throughout most of the year. Therefore, the periods January 1, 2013 to December 31, 2014, and January 1, 2016 to June 30, 2018 are representative of normal operation during the baseline period, and it was determined that SO₂ emissions during that period are also representative. In June 2016, Unit 1 SOFA upgrades were completed for the purpose of reducing NO_x emissions; thus, the representative baseline period for NO_x emissions was determined to be from July 1, 2016 to June 30, 2018.

Baseline annual SO₂ and NO_x emissions were determined based on data obtained from the Coyote Unit 1 continuous emissions monitoring system (CEMS) that was reported to EPA's Clean Air Markets. The annual average emission rate during the representative time period was used to establish baseline annual emissions (in terms of tons per year). Representative baseline emission factors (in terms of pounds per million British Thermal Units (lb/MMBtu)) were developed using baseline annual average emissions and the respective baseline heat inputs. Table 4-1 provides a summary of the Coyote Unit 1 SO₂ and NO_x representative baseline emissions; additional details are included in Appendix A.

Table 4-1. Coyote Unit 1 Baseline Emissions

Pollutant	Baseline Controls	Emissions		Heat Input	Notes
		lb/MMBtu	tons/yr	MMBtu/yr	
SO ₂	DFGD/FF	0.85	12,994	30,562,287	SO ₂ emissions based on annual average tpy for period January 2013-June 2018 (excluding 2015)
NO _x	SOFA	0.46	7,363	32,301,802	NO _x emissions based on annual average tpy for period July 2016 to June 2018 (post-SOFA upgrades)

5. SO₂ AND NO_x CONTROL MEASURES

S&L used a top-down approach to identify and evaluate the technical feasibility and effectiveness of potentially available SO₂ and NO_x control measures. S&L followed Steps 1 thru 3 of the top-down approach described in the BART Guidelines to identify all available retrofit emission control measures, eliminate technically infeasible options, and evaluate the effectiveness of the technically feasible options.²² A brief description of each step is provided below.

Step 1 - Identify All Available Control Options

Available control options are those air pollution control technologies with a practical potential for application to the emission unit and the regulated pollutant under evaluation. Air pollution control technologies can include a wide variety of available methods, systems, and techniques for control of the affected pollutant, and include not only existing controls for the source category but also take into account technology transfer of controls that have been applied to similar source categories and gas streams. Technologies which have not been applied to (or permitted for) full scale operations need not be considered as available.²³

In an effort to identify all potentially available emission control technologies, S&L searched a broad range of information sources including, but not necessarily limited to:

- EPA's RACT/BACT/LAER Clearinghouse;
- EPA's New Source Review (NSR) and Clean Air Technology Center (CATC) Web sites;
- BART evaluations prepared during the initial Regional Haze planning period;
- Information from control technology vendors and engineering/environmental consultants;
- Federal and State NSR permits and Best Available Control Technology (BACT) determinations for similar sources; and
- Technical journals, reports, newsletters and air pollution control seminars.

Step 2 - Eliminate Technically Infeasible Control Options

In Step 2, S&L evaluated the technical feasibility of the control options identified in Step 1 with respect to source-specific and unit-specific factors. Control technologies are technically feasible if either: (1) they have been

²² See, 40 CFR Part 51 Appendix Y, Section IV.D.

²³ Id., at IV.D.1.

installed and operated successfully for the type of source under review under similar conditions; or (2) the technology could be applied to the source under review. In order for a control option to be technically feasible, it must be “available” and “applicable” to the source under consideration. A technology is considered “available” if the source owner may obtain it through commercial channels. An available technology is “applicable” if it can reasonably be installed and operated on the source type under consideration.²⁴

Control technologies that are technically infeasible (i.e., not available or not applicable to the source under consideration) are eliminated for further evaluation. A demonstration of technical infeasibility must be based on physical, chemical and engineering principals, and must show that technical difficulties would preclude the successful use of the control option on the emission unit under consideration. The economics of an option are not considered in the determination of technical feasibility/infeasibility.

Step 3 - Evaluate Technically Feasible Control Technologies for Effectiveness

Step 3 involves evaluating the control effectiveness of all the technically feasible control alternatives identified in Step 2 for the pollutant and emissions unit under review. Control effectiveness should be expressed using a metric that ensures an “apples-to-apples” comparison of emissions performance levels among options, and is generally expressed as the rate that a pollutant is emitted after installation of the control measure. Control technology evaluations for existing sources should consider ways to improve the performance of existing control devices. Special circumstances pertinent to the specific unit under review should be identified and taken into consideration when assessing the capability of the control alternative and determining control effectiveness.

For this evaluation, S&L assessed the technically feasible SO₂ and NO_x control options for effectiveness on Coyote Unit 1. As discussed above, Coyote Unit 1 is an existing cyclone boiler designed to fire North Dakota lignite. The unit is equipped with SOFA for NO_x control, and dry FGD and FF for SO₂ and PM control.

²⁴ A more detailed description of control technology “availability” and “applicability” is provided in 40 CFR Part 51 Appendix Y, Section IV.D.2.

5.1 SO₂ EMISSIONS CONTROLS

5.1.1 Identify Available SO₂ Control Options

Based on a review of available SO₂ control technologies, as well as operational practices and equipment upgrades implemented on existing control systems, potentially available options to control SO₂ emissions from Coyote Unit 1 are listed in Table 5-1.

Table 5-1. Available SO₂ Control Options

SO ₂ Control Technologies
Fuel Switching
Existing DFGD Operational Improvements
Existing DFGD Equipment Upgrades
Existing DFGD + Dry Sorbent Injection (DSI)
Existing DFGD Operational Improvements + DSI
Retrofit New Dry FGD
Retrofit New Wet FGD

5.1.2 Technical Feasibility of Available SO₂ Control Options

Potentially available SO₂ control options identified in Table 5-1 were evaluated for technical feasibility (i.e., availability and applicability to Coyote Unit 1) based on a review of physical, chemical, and engineering principals, and an assessment of commercial availability. Options determined to be technically infeasible, or options that have no practical application to Coyote Unit 1, were eliminated from further review. S&L evaluated the effectiveness of the control options determined to be technically feasible, and established an emissions performance level (i.e., control emissions rate) for each.

5.1.2.1 Fuel Switching

One potential strategy for reducing SO₂ emissions is to reduce the sulfur content of the coal. Limiting the amount of sulfur in the coal directly limits the amount released during the combustion process, and would reduce SO₂ loading to the dry scrubber. Coyote Unit 1 is a cyclone boiler designed to fire North Dakota lignite as the primary fuel. Lignite fired at the Coyote Station is mined and supplied to the station from the nearby Coyote Creek Mine. The mine, which is owned and operated by Coyote Creek Mining Company, has primary mining operations

approximately 3-4 miles southwest of Coyote Station and can be considered a mine mouth plant. Previous regulatory and court decisions have concluded that requiring a mine mouth facility to evaluate low sulfur coal would require the facility to redefine its fundamental purpose and design; therefore, fuel switching can be rejected as an available control option.²⁵ Because the use of North Dakota lignite from the Coyote Creek Mine is an inherent aspect of Coyote operation, fuel switching will not be evaluated.

5.1.2.2 Existing DFGD Operational Improvements and Equipment Upgrades

Operational and other design changes/upgrades to the existing dry scrubber may provide an opportunity for additional SO₂ removal and allow the unit to achieve lower controlled SO₂ emissions. S&L, working with OTP personnel, identified a number of potentially feasible operational changes that may be available to increase SO₂ removal efficiency with the existing equipment. Potentially available operational and design changes to the existing control system are summarized in Table 5-2. A detailed discussion of each of these options is provided in the following sections.

Table 5-2. FGD Operational Improvements and Equipment Upgrades

FGD Operational Improvements
Lime Quality
Ca:S Stoichiometric Ratio
Approach to Saturation Temperature
FGD Design Changes and Equipment Upgrades
Atomizer Replacement
Slaker Replacement
Adding an Absorber Module
Replacing Existing Absorbers with New Absorber Modules

Lime Quality

The quantity of lime (CaO) available in a dry scrubbing system compared to the amount of SO₂ entering the system is called the stoichiometric ratio (generally referenced as the Ca:S stoichiometric ratio). Reagent quality directly

²⁵ In re: Prairie State Generating Company, PSD Appeal No. 05-05, Slip. Op. at 36 (2006)

affects the Ca:S stoichiometric ratio in DFGD control systems. Using a high quality lime increases the availability of hydrated lime to support process chemistry, and reduces the lime slurry injection rate needed for SO₂ removal.

Lime quality is measured both by the CaO content and reactivity of the lime product. In a dry scrubber, CaO is combined with water to form hydrated lime or calcium hydroxide (Ca(OH)₂), which provides the calcium that is needed to react with SO₂ in the flue gas. With a higher quality lime, more calcium hydroxide is available to react with SO₂. Lime products with a CaO content of 90% or greater are generally considered high quality lime. Lower quality lime products have a lower CaO content and higher quantity of inert material. Reactivity of the lime is measured by the temperature rise when the lime is slaked (i.e., water addition). In general, porous lime products have higher reactivity which is demonstrated by achieving a temperature rise of approximately 40 °C within 3 minutes of adding water.

Based on a review of available lime analyses, and a review of operating data from the existing lime slaking system, Coyote Unit 1 currently procures a high quality lime for use in the dry scrubbers. The typical CaO content of the lime used at Coyote is 90% or greater, and when slaked can achieve a 39.4 °C temperature rise in 3 minutes of adding water. For these reasons, changing the lime quality is not considered a technically feasible operational change available to control SO₂ emissions from Coyote Unit, and will not be evaluated further.

Ca:S Stoichiometric Ratio

Other operational changes that may be available to increase the Ca:S stoichiometry in the existing dry scrubber include: (1) increasing the byproduct recycle rate; and/or (2) increasing the quantity of fresh hydrated lime introduced to the system. Due to the cost savings that may be realized with the first option, some facilities with existing DFGD controls have opted to increase solids recycle rates to as high as 40-50% solids to achieve an incremental increase in SO₂ reduction, if capacity was available in the byproducts handling system. If capacity is not available, increasing fresh lime addition to the system may also be a viable option to increase the Ca:S stoichiometric ratio.

Solids from a dry scrubber consist of fly ash, reaction byproduct, and residual unreacted hydrated lime. On Coyote Unit 1, solids collected in the fabric filter hoppers are conveyed to either a dry storage silo for disposal or to a recycle fly ash silo where it is used as make-up for the reactant slurry. The recycle system is designed to utilize a portion of the unreacted lime rather than disposing of all of the solids. Recycle solids are combined with the fresh lime addition to provide the makeup lime needed for SO₂ reduction. Increasing the recycle rate can increase the

amount of hydrated lime added to the system (i.e., stoichiometric ratio) without increasing the quantity of fresh lime added to the system.

Based on information provided by the station, the DFGD system on Coyote Unit 1 currently operates the recycle system at approximately 24% solids. The Coyote Unit 1 recycle system is operating within the original design conditions and system capacity. The plant has tested higher recycle rates (up to 28-30% solids), but at these higher rates plant personnel reported significant problems with the atomizer wheels spilling over and pluggage of various strainers. Based on the adverse operational impacts observed during these tests, as well as the design limitations of the existing dry scrubber modules, increasing the recycle % solids is not considered a technically feasible SO₂ control option for Coyote Unit 1.

As an alternative to increasing the recycle rate, the Ca:S stoichiometric ratio in the system may be increased by increasing the quantity of fresh lime introduced to the system. Testing was completed in October 2018 on Coyote Unit 1 to determine the impact of increasing the amount of fresh lime slurry fed to the atomizer feed tanks while adjusting the amount of recycle slurry in order to maintain the design 24% solids to the absorber. During the test program Coyote Unit 1 was able to achieve an average controlled SO₂ emission rate of 0.50 lb/MMBtu without significant adverse operational impacts and represents an average emission rate that Coyote would be expected to achieve on an on-going long-term basis under normal operating conditions. The emission rate should not be construed to represent proposed permit limits. Corresponding permit limits must be evaluated on a control system-specific basis; however, an additional 10-15% margin would likely be needed to account for operating margin.

Increasing the quantity of fresh lime introduced to the system will require the existing atomizer wheels to be upgraded from the eight (8) nozzle wheel to a twelve (12) nozzle wheel to mitigate for potential plugging and spill-over issues caused by the percent solid limitation of the existing atomizer wheels (see, Section 5.1.2.2 Atomizer Replacement), and to prevent the possibility of moisture carry-over that could occur with the increase in lime slurry flow. Although upgrades to the existing atomizer wheels and nozzles will be required, increasing the Ca:S stoichiometric ratio by adding additional fresh lime to the system is considered a technically feasible SO₂ control option for Coyote Unit 1, and will be included in the Four Factor Analysis.

Approach to Saturation Temperature

The reaction of SO₂ with Ca(OH)₂ in a dry scrubber is driven by the absorber temperature. Water surrounding the lime slurry droplet allows SO₂ to dissolve into the liquid and facilitates the reaction between lime and SO₂. The

temperature differential between the inlet and the outlet of the DFGD is used as a driving force for SO₂ removal; however, outlet temperatures must be maintained above the saturation temperature to ensure byproducts exiting the absorber module are dry. Residence time within the absorber vessel, drying time, and exit temperature are all important design parameters for a dry scrubbing system.

Inlet temperature to the dry scrubbing module is relatively constant; therefore, temperature differential across the module is a function of the outlet temperature. As a general rule-of-thumb, the closer the outlet temperature is to the adiabatic saturation temperature, the higher the SO₂ removal efficiency.

Operating a dry scrubbing system at outlet temperatures significantly above the adiabatic saturation temperature accelerates water evaporation from the reactant slurry, limits SO₂ absorption into the droplet, and limits the reaction between the lime and SO₂. Reducing the temperature in the absorber closer to the saturation point can provide additional SO₂ removal. On the other hand, the absorber module may not have sufficient residence time to dry all slurry droplets if the system is operated too close to adiabatic saturation, which would result in deposits in the absorber module, corrosion, and severe operational problems. Therefore, maintaining an absorber outlet temperature close to the point of saturation, while staying above it, is vital for optimal reaction kinetics.

The Coyote Unit 1 dry scrubbers currently operate at an outlet temperature of 190-210 °F, which is approximately 55-75 °F above the adiabatic saturation temperature and within original the OEM design steady state operating parameter of 190°F at the stack. More recent dry scrubbing systems have been designed to operate at 30 °F approach to adiabatic saturation. The station has attempted to lower the outlet temperatures to 165-170°F, however, this change caused significant corrosion of the absorber vessels and downstream equipment. Corrosion was likely due to the fact that the Coyote Unit 1 scrubbers were not able to completely dry the slurry droplets because the absorber vessels were designed with a residence time of approximately 1.0 second. More recent dry scrubbers are designed with approximately 10 seconds of residence time.

Figure 5-1 provides a simplified drawing of the Coyote Unit 1 scrubber compared to more recent DFGD designs, and depicts the arrangement limitation causing Coyote's shorter residence time. The low residence time limits the scrubbers ability to dry all slurry droplets when the system is operated too close to the approach to adiabatic saturation temperature. Due to the design limitations of the existing absorber vessels, reducing the outlet temperature is not considered a technically feasible SO₂ control option for Coyote Unit 1, and will not be evaluated further.

Figure 5-1. Comparison of Typical SDA/FF and Coyote Unit 1 SDA/FF Arrangement

Atomizer Replacement

Spray droplet size is an important parameter in the design and operation of a dry scrubber, and can improve lime utilization and SO_2 removal. Finer spray will increase the surface area of the slurry droplets exposed to the flue gas. Greater surface area increases the potential for SO_2 to absorb into the moisture of the slurry droplets. Droplet fineness also plays a role in particle drying time. Larger droplets can have a negative effect on the slurry drying time which can lead to moisture carryover to downstream equipment causing buildup and corrosion.

The Coyote Unit 1 dry scrubber, provided by Combustion Engineering, is designed with three (3) rotary atomizers, each with an eight (8) nozzle wheel in each absorber module to achieve a fine slurry spray. The design of the atomizer and speed at which the wheel rotates are controlling factors for the size and form of the droplets in the spray. The design and speed of atomizers is highly dependent on the spray pattern needed to mix with the hot flue gas in the scrubber module for optimum absorption of SO_2 while also preventing wetting of the absorber walls.

Based on S&L's assessment of the existing control system, previous testing completed by the station, and input from station operators, the existing DFGD system is limited in residence time, and the ability to increase the recycle ratio (solids content) to allow for more effective Ca:S contact in the scrubber vessels. The existing atomizers with eight (8) nozzle wheels would need to be upgraded to a twelve (12) nozzle wheel to mitigate for potential plugging and spill-over issues that could occur with the increased Ca:S stoichiometric ratio (discussed in Section 5.1.2.2). Based on engineering judgment, new 12 nozzle atomizers would improve spray atomization to produce slurry droplets that are smaller in size than the droplets produced by the existing nozzle design. Improved materials of construction would also allow for higher solids content in the slurry without detrimental equipment pluggage or spill-over.

Replacing the existing nozzles with a more recent 12 nozzle wheel design would provide better atomization of the slurry spray and allow for more effective Ca:S contact in the absorber vessels. However, nozzle replacement would not, on its own, be expected to provide a significant increase in SO₂ control. Nozzle upgrades coupled with operational changes designed to increase the Ca:S stoichiometric ratio is a technically feasible option that would be expected to provide additional SO₂ control (See, Section 5.1.2.2 Ca:S Stoichiometric Ratio).

Slaker Replacement

Lime slurry, the reagent used for SO₂ removal in a dry scrubber, is produced by mixing pebble lime with heated water in a slaker; this process is referred to as “slaking”. The slaker is operated at an optimum water-to-lime ratio (typically between 3:1 and 6:1) to produce lime slurry by metering the amount of water and the amount of lime added to the slaker. Slakers are typically designed to produce a lime slurry between 15-20% solids. The lime slurry is added to recycle slurry in a mix tank and then sent to the atomizer where it is sprayed into the scrubber for SO₂ removal.

Coyote Unit 1 still operates the original Dorr-Oliver detention slakers. The slakers operate at a 5:1 water-to-lime ratio and approximately 18% solids, which is in line with the design as well as industry practice. Therefore, replacing the slakers would not result in improved Ca:S contact in the absorber vessels or provide additional SO₂ removal. Replacing the lime slakers is not considered a technically feasible SO₂ control option for Coyote Unit 1, and will not be evaluated further.

Adding an Absorber Module

Another option for extending the residence time within the reactor modules and increasing Ca:S contact would be to add an additional absorber module. The existing system is designed with four absorber modules that share three fabric filter zones. The system is designed to operate with four modules at full load, three or four modules at 75% load and two modules at 50% load. At full load, the flue gas residence time in the reactor modules is approximately 1.0 second. More recent dry scrubbing systems have been designed with reaction vessel residence times of 10 seconds or more.

One potential option available to the Coyote Station to increase absorber module residence time would be to add an additional absorber module to the existing dry scrubbing system. The number of absorber modules used in a DFGD system is dependent on multiple operating parameters, including the flue gas flow rate and SO₂ concentrations. DFGD absorber modules are typically specified with minimum and maximum flue gas flow rates. If the absorber

modules are oversized, flue gas velocities through the module can be too low, causing solids dropout inside the vessel. If the absorber modules are undersized, flue gas velocities can be too high, causing residence time to fall below recommended levels.

Dry scrubbing units that are operating at flue gas volumes significantly above the design flow rate can benefit from adding an extra module to the system. The module would be placed in parallel with the existing modules to achieve a similar pressure drop through each vessel and to ensure equal flue gas distribution to the vessels. Although adding an absorber module would likely allow additional residence time for the SO₂ removal reactions to occur, it would require extensive engineering and modifications to the existing system. More importantly, the Coyote Unit 1 absorber module design is no longer available from Combustion Engineering, and it would likely not be possible to procure a commercial offering from another technology vendor that would be compatible with the existing modules. Therefore, incorporating an additional absorber module into the existing system is not a commercially available or technically feasible SO₂ control strategy for Coyote, and will not be evaluated further.

Replacing Existing Absorbers with New Absorber Modules

Replacing the existing modules with new absorber modules would require significant engineering and facility modifications. Based on a preliminary review of the control system layout, the only practical location for this option would be to construct the new vessels in the same location as the existing modules. Locating the new modules adjacent to the existing absorber modules would require flue gas to be redirected from the air heater outlets to the new absorbers and back to the existing fabric filters, which would likely result in significant solids dropout and other operational issues. Therefore, locating the new absorber modules adjacent to the existing absorber modules is not considered a technically feasible option.

Installing the new absorber vessels in the same location as the existing dry scrubber modules would require Coyote Unit 1 to be taken off-line for an extended period of time. OTP could not operate the unit while the existing modules were dismantled and removed, or while the new absorber modules, duct work, and other system tie-ins were installed. Based on construction schedules for new DFGD systems, and taking into consideration decommissioning of the existing dry scrubber modules, this option would likely require an outage of at least 12-months and would require Coyote to purchase replacement power during this period. In comparison, a typical major outage at Coyote Station is only 6-8 weeks. Outage costs would add significantly to the cost of this control option.

Although replacing the existing dry scrubber modules with new DFGD reactor vessels would require a long outage, there is no technical basis for eliminating this option from the analysis. Replacing the exiting dry scrubber modules with new absorber modules would address the design and operational limits of the existing system. The new absorber modules could be designed to provide additional Ca:S contact and residence time between the exhaust gas and the slurry, and would likely allow OTP to reduce the approach to saturation temperature, design parameters which would increase overall SO₂ removal.

Coyote Unit 1 consistently achieves overall removal efficiencies in the range of approximately 65-73% with the existing dry scrubbing system. Based on engineering judgment and industry practice, it is expected that the fabric filter provides approximately 10-15% of the overall removal in the DFGD system. Assuming 10-15% removal in the fabric filter, approximately 60% of the SO₂ removal is achieved in the existing absorber modules based on the current coal sulfur content. Estimated SO₂ removal efficiencies across the existing DFGD system are shown in Table 5-3.

Table 5-3. Existing SO₂ Removal Efficiencies

Existing Scrubber Modules	Existing Fabric Filter	Overall
Inlet: 2.83 lb/MMBtu Outlet: 1.14 lb/MMBtu Efficiency: 60% of uncontrolled Contribution: 85% of overall removal	Inlet: 1.14lb/MMBtu Outlet: 0.85 lb/MMBtu Efficiency: 11% of uncontrolled Contribution: 15% of overall removal	Inlet: 2.83 lb/MMBtu Outlet: 0.85 lb/MMBtu Efficiency: 70%

Based on SO₂ removal efficiencies achieved in practice on existing units equipped with DFGD, it is anticipated that replacing the existing absorber modules with new scrubber modules could increase removal across the scrubber to approximately 80%, and increase overall removal efficiencies to approximately 91%. It should be noted that Coyote is expected to receive higher sulfur content coal in the future; therefore, the new scrubber vessel SO₂ removal analysis is based on this higher sulfur content coal. The removal efficiencies for this option are shown in Table 5-4.

Table 5-4. New Scrubber Vessel SO₂ Removal Efficiencies

New Scrubber Modules		Existing Fabric Filter	Overall
Inlet:	3.12 lb/MMBtu ^(Note 1)	Inlet:	0.62 lb/MMBtu
Outlet:	0.62 lb/MMBtu	Outlet:	0.29 lb/MMBtu
Efficiency:	80% of uncontrolled	Efficiency:	11% of uncontrolled
Contribution:	88% of overall removal	Contribution:	12% of overall removal
			Inlet: 3.12 lb/MMBtu Outlet: 0.29 lb/MMBtu ^(Note 2) Efficiency: 91%

Note 1. Inlet SO₂ rate based on anticipated future fuel sulfur content.

Note 2. Emission rates shown represent average emission rates that the control options would be expected to achieve on an on-going long-term basis under normal operating conditions for Coyote Unit 1. Emission rates are provided for comparative purposes, and should not be construed to represent proposed permit limits. Corresponding permit limits must be evaluated on a control system-specific basis; however, an additional 10-15% margin would likely be needed to account for operating margin.

Replacing the existing dry scrubber modules with new absorber modules is a technically feasible control technology option that would provide an incremental increase in overall SO₂ removal efficiency. However, this option would require Coyote Unit 1 to be taken off-line for an extended period of time (approximately 12 months). Outage costs associated with the extended outage are included in the four-factor cost impact evaluation for this option. Given the constructability issues and extended outage requirements associated with replacing the existing dry scrubber modules, this may not be a practical option for Coyote; nevertheless, it will be included as a technically feasible SO₂ control option in the Four Factor Analysis.

5.1.2.3 Existing FGD + Dry Sorbent Injection

Alkali based sorbent injection is a proven technology for the removal of sulfur trioxide (SO₃) and other acid gases from coal-fired power plant flue gas, and can be used to provide SO₂ control. Sorbent is injected into the ductwork after the furnace and prior to the particulate collection device, where it reacts with SO₂ and other acid gases. Sorbent injection systems are relatively simple systems consisting of material storage, feeding mechanism, blower or transfer line, and an injection device. For SO₂ control on Coyote Unit 1, sorbent would be injected upstream of the dry scrubber to provide an incremental reduction in the concentration of SO₂ in the flue gas at the inlet to the dry scrubber.

Sorbents react with SO₂, and other acid gases, in the flue gas when injected at an appropriate rate and within the proper temperature range for that sorbent. The resulting particulate matter is removed from the flue gas by the particulate control system. The process works through neutralization of the acid gases with the alkaline sorbent. The neutralization reaction occurs as long as the sorbent remains in contact with the gas in the flue gas duct work within the required temperature range.

Dry sorbents that have been used for SO₂ control on coal-fired boilers include:

- Hydrated Lime (Ca(OH)₂)
- Trona or Sodium Bicarbonate (SBC)

The following wet sorbents have also been used for acid gas control at coal-fired power generating stations:

- Sodium Bisulfite (SBS)
- Soda Ash

Dry sorbents, including hydrated lime, Trona, and SBC would be injected pneumatically as a dry powder into the flue gas ductwork upstream of the Coyote Unit 1 dry scrubber. Trona and SBC are both sodium-based sorbents, which react with SO₂ to form sodium salts. Hydrated lime would react with SO₂ to form calcium sulfate salts. The hydrated lime reactions are the same reactions that are taking place in the existing dry scrubber.

Hydrated lime is less reactive than the sodium based dry sorbents; thus, higher injection rates and longer residence time would be required to achieve the same removal efficiency. However, hydrated lime has a lower unit cost compared to other sorbent options, offsetting the higher injection rates. It is also important to note that the hydrated lime chemistry involves the same reactions, and forms the same calcium salts, as those currently taking place in the dry scrubber reaction vessels. Therefore, using hydrated lime as the sorbent would not introduce any new constituents into the dry scrubbing system, and could potentially increase the Ca:S stoichiometry in the dry scrubber.

Because of the higher reactivity of sodium based sorbents, less reactant may be required to achieve the same removal efficiency; however, injecting a sodium-based sorbent into the flue gas upstream of the Coyote Unit 1 dry scrubber would introduce new chemical constituents into the scrubber and into the fly ash/scrubber byproduct material. This could prove problematic as sodium compounds are water soluble, and introducing sodium into the system could adversely affect the characteristics of the byproduct solids generated by the system. Detailed studies and demonstration tests would be needed to ensure that introducing relatively large amounts of sodium would not adversely affect scrubber operation or result in solids disposal issues.

SBS and soda ash (Na₂CO₃) injection are wet injection technologies typically used for SO₃ mitigation. SBS and soda ash can be injected into the flue gas upstream or downstream of the air heater as a 10% solution (by weight) using dual fluid atomizers. Both products will react with SO₂ and SO₃ to form sodium salts, which can be collected in the downstream particulate collection device. URS/Codan Associates own the patent for this SBS control process. Based on conversations with URS, their SBS technology is generally more economical using soda ash,

and all recent projects have used soda ash. However, as with the dry sodium-based injection systems, these systems would introduce sodium into the Coyote Unit 1 DFGD control system.

Sorbent injection (dry or wet) upstream of the existing dry scrubber is a technically feasible and commercially available SO₂ control option for Coyote Unit 1. Taking into consideration the fact that Coyote is currently equipped with a calcium-based dry scrubbing system, hydrated lime dry sorbent injection would be the most practical, and potentially the most effective, sorbent injection control option. Sodium-based systems would require extensive testing to determine the potential impacts associated with introducing significant quantities of sodium into the existing system, and are not considered practical control options for Coyote Unit 1.

Based on engineering judgment, and assuming adequate residence time in the duct work upstream of the existing dry scrubber, hydrated lime injection could reduce SO₂ concentrations at the dry scrubber inlet by approximately 35%. Based on future design fuel characteristics, this would reduce SO₂ concentrations at the dry scrubber inlet from approximately 3.12 lb/MMBtu to approximately 2.03 lb/MMBtu. Applying the current scrubber SO₂ removal efficiency of 71% (dry scrubber plus fabric filter), would result in a controlled SO₂ emission rate of 0.58 lb/MMBtu. DSI upstream of the existing dry scrubbing system is considered a technically feasible SO₂ control technology; however, flow modeling and field testing at Coyote Unit 1 would be needed to ensure that adequate residence time is available for SO₂ control and to confirm the incremental reduction in SO₂ emissions achievable without creating unacceptable operational issues.

Table 5-5. DSI SO₂ Control Technology Estimated Emissions

	Unit 1
Uncontrolled SO ₂ Emissions (lb/MMBtu)	3.12
SO ₂ Emissions at DSI Outlet (lb/MMBtu)	2.03
SO ₂ Emissions at FF Outlet (lb/MMBtu)	0.58 ¹
Overall Removal (%)	80.4

Note 1. Emissions at the FF outlet were estimate by applying existing 71% SO₂ removal across the DFGD system ($2.03 \text{ lb/MMBtu} \times (1 - 0.71) = 0.58$).

Note 2. Emission rates shown represent average emission rates that the control options would be expected to achieve on an on-going long-term basis under normal operating conditions for Coyote Unit 1. Emission rates are provided for comparative purposes, and should not be construed to represent proposed permit limits. Corresponding permit limits must be evaluated on a control system-specific basis; however, an additional 10-15% margin would likely be needed to account for operating margin.

5.1.2.4 FGD Operational Improvements + DSI

Some of the SO₂ control technologies which involve improvements to the FGD can potentially be applied in combination with dry sorbent injection to provide additional SO₂ removal. This option would be considered a layered technology of the technically feasible FGD operational improvements discussed in Section 5.1.2.2 with dry sorbent injection discussed in Section 5.1.2.3. Technically feasible FGD operational improvements include increasing the Ca:S stoichiometric ratio of the FGD by introducing additional fresh lime to the absorber modules. Based on engineering judgement, layering FGD operational improvements with DSI could reduce SO₂ emissions from the baseline SO₂ emission rate of 0.85 lb/MMBtu to approximately 0.33 lb/MMBtu at Coyote Unit 1 as shown in Table 5-6. However, as stated previously, flow modeling and field testing at Coyote Unit 1 would be needed to ensure that adequate residence time is available for SO₂ control and to confirm the incremental reduction in SO₂ emissions achievable without creating unacceptable operational issues.

Table 5-6. Layered (DSI + Ca:S) SO₂ Control Technology Estimated Emissions

	Unit 1
Uncontrolled SO ₂ Emissions (lb/MMBtu)	3.12
SO ₂ Emissions at DSI Outlet (lb/MMBtu)	2.03
SO ₂ Emissions at FF Outlet (lb/MMBtu)	0.33 ¹
Overall Removal (%)	89.4

Note 1. Emissions at the FF outlet were estimate by applying 84% SO₂ removal across the DFGD system with operational improvements ((2.03 lb/MMBtu x (1 - 0.84 lb/MMBtu) = 0.33 lb/MMBtu).

Note 2. Emission rates shown represent average emission rates that the control options would be expected to achieve on an on-going long-term basis under normal operating conditions for Coyote Unit 1. Emission rates are provided for comparative purposes, and should not be construed to represent proposed permit limits. Corresponding permit limits must be evaluated on a control system-specific basis; however, an additional 10-15% margin would likely be needed to account for operating margin.

5.1.2.5 Install New Dry FGD System

Replacing the existing dry scrubber and fabric filter with new control systems would require significant engineering and modifications to the facility. Based on a preliminary review of the facility layout, the new control systems could be located northeast of Coyote Unit 1's existing dry scrubber/FF. The new DFGD/FF and all auxiliary equipment could be constructed while the unit remains on-line. The control systems could be tied-in to the existing systems during a scheduled major outage.

Various DFGD systems have been designed for use with pulverized coal-fired boilers; including the spray dryer absorber (SDA) and circulating dry scrubber (CDS). Both systems are evaluated in more detail below.

Spray Dryer Absorber / Fabric Filter

SDA systems have been used in large coal-fired utility applications, and have demonstrated the ability to effectively reduce uncontrolled SO₂ emissions from pulverized coal units. Like other dry scrubbing systems, SDA control systems use a slurry of lime and water injected into the reaction modules to remove SO₂ from the combustion gases. The reaction modules are designed to provide adequate contact and residence time between the exhaust gas and the slurry to produce a dry by-product. Process equipment associated with an SDA control system includes an alkaline storage tank, mixing and feed tanks, atomizer assembly, spray chamber module, integrated fabric filter, and solids recycle system. The recycle system collects solid reaction byproducts and recycles them back to the spray dryer feed system to maximize reactant utilization.

Various process parameters affect the efficiency of the SDA process including: the type and quality of the additive used for the reactant, reactant-to-sulfur stoichiometric ratio, how close the SDA is operated to saturation conditions, and the amount of solids product recycled to the atomizer. SDA systems are typically designed to operate within approximately 30 °F adiabatic approach to saturation temperature. Operating closer to the adiabatic saturation temperature may allow for higher SO₂ control efficiencies; however, outlet temperatures too close to the saturation temperature will result in severe operating problems including reactant build-up in the absorber modules, blinding of the fabric filter bags, and corrosion in the fabric filter and ductwork.

SO₂ removal efficiencies in a SDA are also dependent upon good gas-to-liquid contact. Reactant spray nozzle designs are vendor-specific, and include both dual-fluid nozzles and rotary atomizers. The atomizing nozzle assembly is typically located in the SDA penthouse and flange mounted to the roof of the absorber vessel.

Replacing the existing dry scrubber/FF with a new SDA/FF control systems is a technically feasible and commercially available control option on Coyote Unit 1. SDA/FF control systems are generally installed on units that burn lower sulfur fuels (i.e., < 3 lb SO₂/MMBtu) because design limitations, including Ca:S stoichiometry, residence time, and approach to saturation typically limit total SO₂ removal to approximately 95%. This removal efficiency represents what the control system vendor would be willing to guarantee upon initial operation of the system. On Coyote Unit 1, 95% removal would result in an average controlled SO₂ emission rate of approximately 0.16 lb/MMBtu.

Circulating Dry Scrubber / Fabric Filter

A second type of dry scrubbing system is the circulating dry scrubber (CDS). Similar to other dry flue gas desulfurization systems, the CDS system would be located after the air preheater, and byproducts from the system collected in an integrated fabric filter. Unlike the SDA systems, CDS systems use a circulating fluidized bed of hydrated lime reagent to remove SO₂ rather than an atomized lime slurry; however, similar chemical reaction kinetics are used in the SO₂ removal process.

In a CDS, flue gas is treated in an absorber vessel where the flue gas stream flows through a fluidized bed of hydrated lime and recycled byproduct. Water is injected into the absorber through a venturi located at the base of the absorber for temperature control. Flue gas velocity through the vessel is maintained to keep the fluidized bed of particles suspended in the absorber. Water sprayed into the absorber cools the flue gas from approximately 300 °F at the inlet to the scrubber to approximately 160 °F at the outlet of the fabric filter. The hydrated lime absorbs SO₂

from the gas and forms calcium sulfite and calcium sulfate solids. Desulfurized flue gas passes out of the absorber, along with the particulate matter (reaction products, unreacted hydrated lime, calcium carbonate, and the fly ash) to the fabric filter.

As with the SDA/FF option, replacing the existing dry scrubber/FF with a new CDS/FF control system would require significant engineering and modifications to the existing facility. For this evaluation it was assumed that the CDS/FF control systems could be located adjacent to the existing dry scrubber/FF, and that the control systems could be tied-in to the existing system during a scheduled major outage.

Replacing the existing dry scrubber and FF with a new CDS/FF control system is a technically feasible and commercially available control option for Coyote Unit 1. Based on engineering judgment, it is anticipated that the retrofit CDS/FF control option would achieve SO₂ removal efficiencies higher than those achieved with a SDA/FF due to the increased Ca:S contact in the fluidized bed absorber vessel. Based on recent CDS retrofit projects, and taking into consideration expected fuel characteristics, it is anticipated that the retrofit CDS/FF control system could achieve SO₂ removal efficiencies of approximately 97%. This removal efficiency represents what the control system vendor would be willing to guarantee upon initial operation of the system. On Coyote Unit 1, 97% removal would result in an average controlled SO₂ emission rate of approximately 0.09 lb/MMBtu and represents an average emission rate that Coyote would be expected to achieve on an on-going long-term basis under normal operating conditions. The emission rate should not be construed to represent proposed permit limits. Corresponding permit limits must be evaluated on a control system-specific basis; however, an additional 10-15% margin would likely be needed to account for operating margin.

5.1.2.6 Install New Wet FGD System

Another option available to the Coyote Station would be to replace the existing dry scrubbing system with a new wet FGD control system located downstream of the existing FF.

Wet FGD technology is an established SO₂ control technology. Wet scrubbing systems have been designed to utilize various alkaline scrubbing solutions including lime, limestone, and magnesium-enhanced lime. Wet scrubbing systems have also been designed with spray tower reactors and with reaction vessels (e.g., jet bubbling reactor). Although the flue gas/reactant contact systems may vary, the chemistry involved in all wet scrubbing systems is essentially identical. All wet scrubbing systems use an alkaline slurry that reacts with SO₂ in the flue gas to form insoluble calcium sulfite (CaSO₃) and calcium sulfate (CaSO₄) salts.

A large majority of the wet FGD systems designed to remove SO₂ from existing high-sulfur utility boilers have been designed as wet limestone scrubbers with spray towers and forced oxidation systems. Therefore, for this evaluation, it was assumed that the WFGD control system would be designed as a limestone spray tower scrubber with forced oxidation. Other potentially available wet scrubber designs are not included in this evaluation because the chemistry involved in all wet scrubbing systems are essentially identical, alternative designs would not provide any additional SO₂ control, and control system costs would be similar.

Wet Limestone Scrubbing

In a wet limestone scrubbing system, limestone (CaCO₃) is mixed with water to formulate the alkali scrubber slurry. Flue gas enters the absorber vessel and contacts the absorbent slurry in a countercurrent spray tower. SO₂ in the flue gas reacts with the limestone slurry to form insoluble calcium sulfite (CaSO₃) and calcium sulfate (CaSO₄) which is removed as a solid waste by-product. Spent absorbent is returned to the reaction tank where dissolved sulfur compounds are precipitated as calcium salts. Fresh limestone slurry is added to regenerate the spent absorbent.

The reaction tank is sized to provide sufficient time for precipitation of the sulfur compounds. From the reaction tank, regenerated absorbent slurry is recycled to the absorber. The slurry typically contains from 5 to 15% suspended solids consisting of fresh additive, absorption reaction products, and lesser amounts of fly ash. To regulate the accumulation of solids, a bleed stream from the reaction is routed to the solid/liquid separation equipment.

Forced oxidation of the scrubber slurry may be used with limestone WFGD systems to produce calcium sulfate solids (gypsum) instead of the calcium sulfite by-product. Air blown into the reaction tank provides oxygen to convert most of the calcium sulfite (CaSO₃) to a relatively pure gypsum. Forced oxidation of the scrubber slurry provides a more stable by-product and reduces the potential for scaling in the spray tower. The gypsum by-product from this process must be dewatered, and may be salable if a local market for gypsum is available, reducing the quantity of solid waste that needs to be landfilled.

For this evaluation it was assumed that the existing Coyote Unit 1 dry scrubber reactor vessels would remain in place, and that the WFGD control system would be located downstream of the existing FFs and ID fans, most likely northeast of the unit's existing dry scrubber/FF. Dry scrubber reactor vessel internals would ultimately be removed to reduce pressure drop through the system. A single WFGD absorber tower would be sufficient for the Coyote

Unit 1 flue gas flow. In addition to the absorber tower and reaction vessel, the WFGD control system would require a limestone handling and preparation system and by-product dewatering systems. Because of the saturated nature of the flue gas exiting the WFGD, a new stack with a liner capable of wet flue gas operation would be required. New booster ID fans would also be required to account for the additional pressure drop through the WFGD control system.

Wet FGD technology is an established SO₂ control technology. Wet scrubbing systems have been installed on units that fire medium to high sulfur coals, and would be a technically feasible SO₂ control option for Coyote Unit 1. Based on engineering judgment and information from control system vendors, it is anticipated that a retrofit WFGD control system on a North Dakota lignite-fired unit would be designed to achieve an SO₂ removal efficiency of approximately 98%. This removal efficiency represents what the control system vendor would be willing to guarantee upon initial operation of the system. On Coyote Unit 1, 98% removal would result in an average controlled SO₂ emission rate of approximately 0.06 lb/MMBtu and represents an average emission rate that Coyote would be expected to achieve on an on-going long-term basis under normal operating conditions. The emission rate should not be construed to represent proposed permit limits. Corresponding permit limits must be evaluated on a control system-specific basis; however, an additional 10-15% margin would likely be needed to account for operating margin.

5.1.2.7 Technical Feasibility Summary

Table 5-7 summarizes the results of the feasibility evaluation of available control options for Coyote Unit 1.

Table 5-7. Technically Feasible SO₂ Control Options

SO ₂ Control Option	Technically Feasible (Yes/No)	Technical Feasibility Summary
Fuel Switching	No	Fuel switching is not considered an available SO ₂ control option for Coyote Unit 1 since the use of North Dakota lignite coal is an inherent aspect of plant operations.
Existing DFGD Operational Improvements:		
Lime Quality	No	Changing lime quality in the existing DFGD control system is not a technically feasible operational change for Coyote Unit 1.
Ca:S Stoichiometric Ratio	Yes	Increasing the Ca:S stoichiometric ratio by increase the quantity of fresh lime to the system is considered a technically feasible option for Coyote Unit 1, assuming the operational change is coupled with atomizer replacement.

SO ₂ Control Option	Technically Feasible (Yes/No)	Technical Feasibility Summary
Approach to Saturation Temperature	No	Due to design limitations, further reducing the absorber module outlet temperature on the existing DFGD control system is not a technically feasible option for Coyote Unit 1.
Existing DFGD Equipment Upgrades:		
Atomizer Replacement	Yes	Replacing the existing atomizers is a technically feasible option for Coyote Unit 1 and would provide additional SO ₂ control if coupled with increasing the Ca:S stoichiometric ratio.
Slaker Replacement	No	Slaker replacement would not be expected to provide additional SO ₂ control, and is not a technically feasible equipment upgrade for Coyote Unit 1.
Adding an Absorber Module	No	Coyote Unit 1 DFGD absorber modules are no longer commercially available, thus, adding an absorber module to the existing system is not a technically feasible SO ₂ control option.
Replacing Existing Absorbers with New Absorber Modules	Yes	Replacing the exiting absorber modules with new absorber modules is a technically feasible SO ₂ control system upgrade for Coyote Unit 1 that would require an approximate 12-month outage.
Existing DFGD + DSI	Yes	Hydrated lime sorbent injection upstream of the existing Coyote Unit 1 absorber modules is a technically feasible SO ₂ control option. Flow modeling and field testing would be needed to confirm that the incremental reduction in SO ₂ emissions is achievable without creating unacceptable operational issues.
Existing DFGD Operational Improvements (Increase Ca:S Stoichiometric Ratio) + DSI	Yes	Combining operational improvements (i.e., increased Ca:S stoichiometric ratio) with hydrated lime sorbent injection is a technically feasible SO ₂ control option for Coyote Unit 1. Flow modeling and field testing would be needed to confirm that the incremental reduction in SO ₂ emissions is achievable without creating unacceptable operational issues.
New Retrofit DFGD (CDS/FF)	Yes	Replacing the existing DFGD control system with a new retrofit DFGD (i.e., CDS/FF) is a technically feasible SO ₂ control option for Coyote Unit 1.
New Retrofit WFGD	Yes	Replacing the existing DFGD control system with a new retrofit WFGD is a technically feasible SO ₂ control option for Coyote Unit 1.

5.1.3 Evaluate Technically Feasible SO₂ Control Options for Effectiveness

The technically feasible SO₂ control technologies are listed in Table 5-8 in descending order of control efficiency. Table 5-8 also provides control option-specific SO₂ emission rates in terms of lb/MMBtu. Emission rates shown in

Table 5-8 represent average emission rates that the control options would be expected to achieve during normal operations.

Table 5-8. Evaluate Technically Feasible SO₂ Control Options for Effectiveness

Control Option	SO ₂ Emission Rate (Note 1) lb/MMBtu	% Reduction from Baseline Emission Rate
Baseline (existing DFGD/FF)	0.85	-
New Retrofit WFGD	0.06	92.9%
New Retrofit DFGD (CDS/FF)	0.09	89.4%
New Retrofit DFGD (SDA/FF)	0.16	81.1%
FGD Upgrades - Replacing Existing Absorbers with New Absorber	0.29	65.9%
DSI + FGD Operational Improvements	0.33	61.2%
FGD Operational Improvements – Increase Ca:S Stoichiometric Ratio	0.50	41.2%
DSI + Existing FGD	0.58	31.8%

Note 1. Emission rates shown in Table 5-8 represent average emission rates that the control options would be expected to achieve on an on-going long-term basis under normal operating conditions for Coyote Unit 1. Emission rates are provided for comparative purposes, and should not be construed to represent proposed permit limits. Corresponding permit limits must be evaluated on a control system-specific basis; however, an additional 10-15% margin would likely be needed to account for operating margin.

5.2 NO_x EMISSIONS CONTROLS

5.2.1 Identify Available NO_x Control Options

Based on a review of available NO_x control technologies installed on existing cyclone coal-fired boilers, as well as operational practices and equipment upgrades implemented on existing control systems, potentially available options to control NO_x emissions from Coyote Unit 1 are listed in Table 5-9.

Table 5-9. Available NO_x Control Options

NO _x Control Technologies
Combustion Optimization
Selective Non-Catalytic Reduction (SNCR)
Rich Reagent Injection (RRI)
SNCR + RRI
Gas Reburn
Innovative Technologies (i.e. NOxStar, Water Injection, LoTOX, PerNOxide, Water Injection)
Selective Catalytic Reduction - High Dust, Low Dust or Tail End Configuration (TE-SCR)

5.2.2 Technical Feasibility of Available NO_x Control Options

Potentially available NO_x control options identified in Table 5-9 were evaluated for technical feasibility (i.e. availability and applicability to Coyote Unit 1) based on a review of physical, chemical, and engineering principals, and an assessment of commercial availability. Options deemed to be technically infeasible, or options that have no practical application to Coyote Unit 1, were eliminated from further review. S&L evaluated the effectiveness of the control options determined to be technically feasible, and established an emission performance level (i.e., controlled emission rate) for each.

5.2.2.1 Combustion Optimization

Coyote Unit 1 is equipped with twelve (12) ten (10) foot cyclones, six (6) on the front wall and six (6) each on the rear wall, two levels of three on each wall. The lignite coal requires a pre-dry system, which conveys the coal through individual crushers and into a cyclone separator for moisture separation. The dried coal is discharged from the bottom of the separator through a rotary seal, while the transport air (with a small quantity of fines) is discharged out the top and into ports above the cyclones. The coal discharged through the bottom rotary seal is blown into the cyclone through a pipe referred to as the "lift line" or known as primary air on most other similar installations. The temperature of the pre-dry air/coal temperature is regulated along with the lift line air by injecting cold (tempering) air into the hot primary air stream to regulate the outlet temperatures.

In 2016, The Babcock and Wilcox Company (B&W) installed fourteen (14) separated overfire air (SOFA) ports (seven on the front and rear wall) and modified the cyclones with smaller re-entrant throats and a $\frac{1}{3}$ – $\frac{2}{3}$ split secondary air damper (each having its own damper) to reduce NO_x emissions. For the SOFA process, the injection of air into the boiler is staged into two zones, in which approximately 5% to 20% of the total combustion air is diverted from the burners and injected through ports located above the top burner level. Staging of the combustion air reduces NO_x formation by two mechanisms. First, staged combustion results in a cooler flame which will reduce the formation of thermal NO_x. Second the staged combustion results in less oxygen reacting with fuel molecules. The degree of staging is limited by operational problems since the staged combustion results in incomplete combustion conditions and a longer flame profile. The units normally operate with the $\frac{1}{3}$ rd damper closed or nearly closed to help recirculate the coal in the cyclone and allows for increased coal retention and improved combustion. Since the SOFA installation, Coyote Unit 1 has achieved average controlled NO_x emissions of approximately 0.46 lb/MMBtu.

Tuning of the cyclone boiler to optimize the combustion process and minimize the generation of NO_x was recently completed at Coyote Unit 1. Tuning was completed by lowering the stoichiometry (i.e., lower the air-to-fuel ratio) in the cyclone barrel and tracking the cyclone combustion stability, while staying within the OEM specifications for best combustion engineering practice. Based on the testing results, Coyote Unit 1 was able to achieve average NO_x emissions of approximately 0.42 lb/MMBtu without obvious impacts to boiler performance and with minimal slagging. Based on the results of the combustion turning tests, combustion optimization is considered a technically feasible NO_x control option.

5.2.2.2 Selective Non-Catalytic Reduction

Selective non-catalytic reduction (SNCR) involves the direct injection of ammonia (NH₃) or urea (CO(NH₂)₂) at high flue gas temperatures (approximately 1,600°F – 2,100°F) in an oxidizing environment. The ammonia or urea reacts with NO_x in the flue gas to produce N₂ and water as shown below.

Flue gas temperature at the point of reagent injection can greatly affect NO_x removal efficiencies and the quantity of NH₃ or urea that will pass through the SNCR unreacted (referred to as NH₃ slip). In general, SNCR reactions are effective in the range of 1,600°F – 2,100°F. At temperatures below the desired operating range, the NO_x reduction

reactions diminish and unreacted NH_3 emissions increase. Above the desired temperature range, NH_3 is oxidized to NO_x resulting in low NO_x reduction efficiencies.

Mixing of the reactant and flue gas within the reaction zone is an important factor to SNCR performance. In large boilers, the physical distance over which reagent must be dispersed increases, and the surface area/volume ratio of the convective pass decreases. Furnace geometry, urea spray coverage, and droplet size must be considered when developing good mixing of reagent and flue gas, delivery of reagent in the proper temperature window, and sufficient residence time of the reagent and flue gas in that temperature window. As the boiler cycles in load, the optimum injection region may change; thus, most facilities require multiple injection zones which are placed in and out of service as the unit ramps in load. This can include modifying the zones of injectors that are operating at different loads and temperatures.

Retractable multinozzle lances (MNLs) are sometimes used to improve SNCR performance, especially if the furnace exit flue gas temperatures are too high. The retractable lances allow injection into the appropriate temperature zone more so than wall injectors, depending on the unit load and temperatures. The MNLs also help improve performance by refining the spray pattern for quicker vaporization of the conveying water. MNLs are often used in conjunction with wall injection to provide optimized coverage while reducing reagent cost.

In addition to temperature and mixing, several other factors influence the performance of an SNCR system, including residence time, reagent-to- NO_x ratio, and fuel sulfur content. Increasing the normalized stoichiometric ratio (NSR) can improve NO_x removal.²⁶ This can be achieved by increasing urea solution flow through the injectors or changing the concentration of urea in the solution. However, too high of reagent injection rates will increase the ammonia slip beyond the recommended 10 ppmvd limit. Above this concentration, there are expected to be major impacts to the formation of ammonia salts on the boiler tube banks, reducing heat transfer efficiency, and air heater baskets, causing corrosion.

SNCR can be applied on cyclone boilers due to having reasonable temperature windows and residence time; however, the potential NO_x reduction is boiler-specific. SNCR has been used as a retrofit NO_x control system of on pulverized coal, fluidized bed boilers, and cyclone boilers. Furthermore, SNCR can be implemented on boilers

²⁶ NSR defines the amount of reagent needed to achieve the targeted NO_x reduction. Based on the reaction equations in 5.2.2.2, two moles of NO_x can be removed with one mole of urea or two moles of ammonia. In practice, more than the theoretical amount of reagent needs to be injected into the boiler flue gas to obtain a specific level of NO_x reduction. This is due to the complexity of the actual chemical reactions involving NO_x and injected reagent and mixing limitations between reagent and flue gas. Factors that influence the NSR value: (1) percent NO_x reduction; (2) uncontrolled NO_x concentration in the flue gas; (3) temperature and residence time available for the NO_x reduction reactions; (4) extent of mixing achievable in the boiler; and (5) allowable ammonia slip.

equipped with low-NO_x burners, overfire air, or SOFA systems. Based on the boiler residence time, temperature profile, and stoichiometry, as well as input from SNCR OEMs, it is estimated that an SNCR system could achieve an average controlled NO_x emission rate of approximately 0.28 lb/MMBtu (approximately 39% below the baseline emission rate of 0.46 lb/MMBtu) at full load while limiting ammonia slip to 10 ppmvd. It should be noted that computational fluid dynamic modeling and temperature mapping of the boiler would be needed to confirm that the incremental reduction in NO_x emission is achievable without creating unacceptable operational issues.

5.2.2.3 Rich Reagent Injection

Similar to SNCR, the concept of rich reagent injection (RRI) is to use a nitrogen-containing additive (e.g., urea) injected into a reducing environment to promote NO_x removal. RRI is a commercial technology for cyclone boilers only. In contrast to SNCR, RRI typically is applied with only one injection level in the lower furnace near the cyclone barrels (temperature window of 2000°F-2600°F). The technology requires a sub-stoichiometric oxygen concentration near the barrels at less than approximately 0.95. This allows for a higher injection rate of reagent without oxidizing the nitrogen-containing reagent to NO_x due to the sub-stoichiometry. Injection at this location also creates lower level of excess NH₃ emissions (NH₃ slip), while injecting at an NSR of 2.0-3.0.

Due to the changes of the lower furnace stoichiometry, RRI is often not a technically feasible option at low loads. Once the stoichiometric ratio increases to >1.0, the potential exists for NO_x generation due to the reaction of NH₃ with oxygen, especially if the injection location and rate is not optimized. Based on these limitations, RRI is considered most effective at full load.

The RRI process is a commercially available process. Based on engineering judgment, RRI is expected to reduce NO_x emissions by approximately 20-40% at Coyote Unit 1 when operating at full load with minimal ammonia slip. However, due to the cyclone combustion temperature window, this technology only provides effective NO_x reduction at or near full load. At low loads, RRI does not provide effective control; however, RRI can be combined with SNCR to provide NO_x control across the full range of normal operating loads. RRI is a technically feasible NO_x reduction option for North Dakota lignite-fired cyclone boilers. However, due to its limited operating conditions and ineffective NO_x reduction at low loads, RRI alone is not considered an available NO_x control option, and will only be evaluated in conjunction with SNCR.

5.2.2.4 SNCR + RRI

While RRI alone will provide beneficial NO_x reduction at full load only, coupling RRI with SNCR can provide a balanced approach to NO_x reduction through all load ranges. Since RRI and SNCR injectors are located at different elevations of the furnace and in different temperature windows, there are not concerns of spatial impacts. The combined system would utilize a relatively high urea injection rate, staged at multiple locations throughout the boiler. The main advantage of this combined system is that the SNCR can provide better NO_x reduction at low load and at a lower NSR than RRI alone; thus, the combined system is expected to provide effective NO_x control across all normal operating load ranges. Coupling RRI and SNCR is considered a technically feasible and commercially available NO_x control technology option on Coyote Unit 1. Based on input from SNCR OEMs and engineering judgment, the control option is expected to achieve an average outlet NO_x rate of approximately 0.20 lb/MMBtu with an ammonia slip of 10 ppmvd. It should be noted that computational fluid dynamic modeling and temperature mapping of the boiler would be needed to confirm that the incremental reduction in NO_x emission is achievable without creating unacceptable operational issues.

5.2.2.5 Gas Reburn

Gas reburn is a retrofit technique that has been used to control NO_x emissions from coal- and oil-fired boilers. Gas reburn involves combustion in three distinct zones within the boiler: (1) a primary combustion zone, where the primary fuel is fired using conventional burners; (2) a reburn zone, where secondary fuel, typically natural gas, is introduced into the boiler; and (3) an OFA burnout zone.

In the primary zone of coal-fired boilers, coal is fired through low-NO_x burners (LNBs), at a rate corresponding to approximately 80% to 90% of the total heat input. Natural gas reburn fuel is then injected above the primary combustion zone under fuel-rich conditions at a rate corresponding to approximately 10% to 20% of the total heat input (on a Btu/hour basis). The fuel-rich reburn zone creates a reducing (substoichiometric) region within the boiler where the natural gas, principally methane (CH₄), breaks down to produce hydrocarbon radicals (CH and CH₂). The hydrocarbon radicals react with NO_x produced in the primary combustion zone to form nitrogen (N₂) and water vapor. Because the natural gas is not completely combusted in the reburn zone, gases exiting the reburn zone will contain considerable CO and unburned hydrocarbons; therefore, additional OFA is introduced above the reburn zone to complete the combustion process.

Critical design parameters that affect the feasibility and performance of a gas reburn retrofit system include: (1) baseline NO_x concentration; (2) reburn zone temperature, residence time, and stoichiometry; (3) OFA burnout zone temperature and residence time; and (4) mixing of the reburn fuel and overfire air with the bulk flue gas.

Gas reburn can have a positive impact on NO_x emissions; however, in order to make a meaningful prediction of the NO_x removal capabilities at Coyote Unit 1, extensive testing would be required because gas reburn performance is significantly dependent upon boiler operating characteristics. More importantly, the lack of natural gas available at the Coyote Station precludes the ability to test and implement this control option on Coyote Unit 1. For these reasons, gas reburn is not considered an available or technically feasible NO_x control technology at Coyote Unit 1.

5.2.2.6 Innovative Technologies

NO_xStarTM

The NO_xStarTM process, also known as selective autocatalytic reduction (SACR), uses a continuous controlled amount of ammonia-based reagent with relatively small amounts of hydrocarbon to reduce NO_x emissions. The hydrocarbon is introduced into the flue gas at the convective pass of the boiler, at elevated temperatures. At the elevated temperatures, the hydrocarbon auto-ignites to form a plasma of free radicals that auto catalyzes the reaction of NH₃ and NO_x to form N₂ and H₂O. The hydrocarbon and ammonia are added through banks of nozzles in the superheat or reheat sections of the boiler. The injection location is determined by the location of the temperature windows for the "plasma creation zone" as well as the reaction zone for the ammonia.

To date, only one full-scale demonstration has been conducted to evaluate the technology on a utility-sized boiler. The process is an emerging NO_x control, and there is limited information available to evaluate its technical feasibility and long-term effectiveness on a large lignite-fired boiler. Potential NO_x removal efficiencies would be a function of NH₃-NO_x mixing, flue gas temperature, flue gas composition, and residence time downstream of the injection lances.

Because this is an emerging technology, extensive design engineering and long-term full scale demonstration testing would be required to evaluate the technical feasibility and effectiveness of the control system on Coyote Unit 1. Detailed design of the lances, mixing, optimization of the reagent supply across the boiler convective pass, flue gas temperatures, and flow distribution would have to be studied. Interference with the tube pendants in the convective pass may also make this more difficult to install. Installing a hydrocarbon distribution grid may

present a problem with large boilers because of the span needed to uniformly distribute the reagent, interference with the tube pendants in the convective pass, and an additional booster fan may be needed. For these reasons, NO_xStar™ is not considered an available or technically feasible NO_x control technology at Coyote Unit 1.

PerNO_xide

PerNO_xide utilizes hydrogen peroxide (H₂O₂) to reduce NO_x emissions. Hydrogen peroxide is injected into the ducts ahead of the air preheater and oxidizes the NO to NO₂, which is then captured in a downstream FGD system. To date, the technology has only been tested on a pilot-scale, and it has not been demonstrated on any coal-fired boilers. It is likely that extensive design engineering and testing would be required to evaluate the scale-up potential and long-term effectiveness of the system on Coyote Unit 1. For these reasons, PerNO_xide is not considered an available or technically feasible NO_x control technology at Coyote Unit 1.

LoTO_x[®]

The LoTO_x system is a gas-phase, low-temperature oxidation system, wherein ozone is injected into the flue gas stream to oxidize NO and NO₂ to N₂O₅ before being removed in a wet scrubber. This highly oxidized species of NO_x is water-soluble and rapidly reacts with water to form nitric acid. The conversion of NO_x to nitric acid occurs as the N₂O₅ contacts liquid sprays in the scrubber. The nitric acid would react with the alkali compounds in the scrubber and would be eliminated via the scrubber waste and byproduct streams. The LoTO_x system requires on-demand ozone generation from a liquid oxygen supply.

The LoTO_x system has been successfully applied in refinery applications; however, there are no full scale installations on coal-fired boilers. According to the control system vendor, a demonstration test was performed on a 25-MW coal-fired boiler which showed effective NO_x removal. However, it is likely that extensive design engineering and testing would be required to evaluate the scale-up potential and long-term effectiveness of the system on Coyote Unit 1. As such, LoTO_x is not considered an available or technically feasible NO_x control technology at Coyote Unit 1.

Water Injection

The principle behind this technology is to inject an atomized water spray into the high-NO_x production zones of a cyclone burner or in the core of the flame for other furnaces. The water spray reduces the temperature and results in lower thermal NO_x production within this combustion zone. Developers claim that water injection through

burners used in tangential-fired and wall-fired units will also reduce flame temperatures and lower thermal NO_x production. However, to date only bench-scale test results are available to evaluate this technology's effectiveness in coal-fired applications. Extensive design engineering, pilot-scale testing, and long-term full scale demonstration testing would be required to evaluate the technical feasibility and effectiveness of the control system on Coyote Unit 1.

Water injection has been used to control the formation of thermal NO_x in combustion turbine applications. However, there is insufficient experience and demonstration data in coal-fired applications. As such, water injection is not considered an available or technically feasible NO_x control technology at Coyote Unit 1.

5.2.2.7 Selective Catalytic Reduction

SCR is a process by which ammonia reacts with nitric oxide (NO) and nitrogen dioxide (NO₂), collectively NO_x, in the presence of a catalyst to reduce the NO_x to nitrogen (N₂) and water. SCR technology has been applied to NO_x-bearing flue gases generated from power generating facilities burning various types of coal, including bituminous, subbituminous, and Texas lignite. The principal reactions resulting in NO_x reduction are:

Because these reactions proceed slowly at typical boiler exit gas temperatures of a coal-fired steam electric generating unit, a catalyst is used to increase the reaction rate between NO_x and ammonia. Depending on the specific constituents in the flue gas, a typical temperature range of 550°F to 780°F is necessary to achieve normal performance of the catalyst. For the typical coal-fired boiler, optimal performance will be in the range of approximately 650°F to 750°F.

In general, there are three candidate SCR configurations that can be employed on coal-fired steam electric generating units. The SCR configuration designations generally describe the location of the SCR reaction vessel in relation to other post-combustion air quality control systems. Candidate SCR configurations include:

- High-dust configuration
- Low-dust configuration
- Tail-end configuration

Each of these configurations is described below as they would be applied at Coyote Unit 1.

High-Dust Configuration

In a high-dust configuration, the SCR reactor is located in the flue gas stream between the economizer outlet and the air heater inlet. This configuration locates the SCR within the inherently optimal temperature range environment for NO_x reduction (i.e., 650°F to 750°F); however, flue gas characteristics at the economizer outlet can also have detrimental effects on the SCR catalyst. As an example, the high-dust SCR configuration exposes the SCR catalyst to high levels of fly ash loading. High levels of fly ash can result in significant erosion of the catalyst, resulting in more frequent cleaning cycles and catalyst replacement. A second major concern with the high-dust configuration at Coyote Unit 1 is the presence of high levels of sodium (both in the vapor-phase and as submicron aerosols) in the North Dakota lignite-derived flue gas. Sodium is a known SCR catalyst poison, and also affects the adhesive and cohesive characteristics of the fly ash, which in turn, would have an adverse effect on the SCR catalyst and reactor vessel.

SCR catalyst deactivation occurs through two primary mechanisms: physical deactivation and chemical poisoning. Physical deactivation is caused by either exposure of the catalyst to excessive temperatures (thermal deactivation) or masking of the catalyst due to entrainment of particulate from the flue gas stream (fouling). Chemical deactivation is caused by either an irreversible reaction of the catalyst with a contaminant in the gas stream (poisoning) or a reversible absorption of a contaminant on the surface of the catalyst (inhibition). Loss of catalyst activity through thermal degradation or poisoning is permanent, and reactivity can only be restored by replacing the catalyst.

In a North Dakota lignite application, SCR catalyst poisoning is expected to result from the presence of trace elements and strong alkaline substances in flue gas, including sodium (Na), potassium (K), and calcium (Ca). Alkaline metals can chemically attach to active catalyst pore sites and cause deactivation. Sodium and potassium are of prime concern especially in their water-soluble forms, which are more mobile and can penetrate into the catalyst pores. Earth metals, especially calcium, can react with SO₃ absorbed within the catalyst to form CaSO₄ and blind the catalyst.

North Dakota lignite contains relatively high levels of organically associated alkali and alkaline-earth elements, including Na, Ca, K, and magnesium. Sodium levels in North Dakota lignite are typically 5 to 20 times higher than sodium levels in bituminous and subbituminous coals, and sodium compounds can represent between 5% and 11% of the ash generated from firing North Dakota lignite. These sodium levels, occurring in both the vapor phase and particulate phase, along with relatively high levels of potassium and calcium, significantly increase the potential for

catalyst deactivation, plugging, and erosion. Based on the ash chemistry, a conventional high dust SCR arrangement would likely experience unacceptable catalyst deactivation rates.

To evaluate deactivation rates on a North Dakota lignite-fired boiler, EERC and several utilities and catalyst vendors conducted pilot scale testing at the Coyote Station in 2003-2004. The pilot scale test reactor SCR deployed at the Coyote Station became plugged and the catalyst pores deactivated after 2 months of operation (approximately 1,430 hours). This deactivation rate is significantly faster than the deactivation rate observed on bituminous and subbituminous coal-fired units, which can achieve catalyst life ranging between 10,000 and 30,000 operating hours. The EERC described the deactivation at the Coyote Station as extremely rapid and severe.²⁷

NDDEQ prepared a comprehensive technical feasibility assessment of high dust SCR on lignite-fired boilers during the first planning period.²⁸ The Department concluded, based on the unique characteristics of North Dakota lignite-derived flue gas, that the high-dust SCR configuration was not a technically feasible or commercially available NOx control option for North Dakota lignite-fired boilers.²⁹ Reasons upon which NDDEQ based its conclusion that high-dust SCR was not a technically feasible option for North Dakota lignite-fired boilers included, but were not limit to:³⁰

- 1) North Dakota lignite³¹ has a higher organic matter content and contains a higher proportion of alkali metal constituents, especially sodium, than subbituminous coal. Approximately 75% of the total sodium in lignite is associated with the organic fraction of the lignite. During combustion, organic and water-soluble sodium vaporizes; consequently, combustion of the coal leads to higher flue-gas concentrations of alkali metals in vapor form.
- 2) The unburned or partially burned organic fraction of North Dakota lignite contains more sodium than other coals. Sodium can react with silicate particles causing a "stickiness" quality to the flue gas ash, resulting in increased ash deposition on heat transfer surfaces. Larger particles can fracture from heat-transfer surfaces (a.k.a. popcorn ash) and enter the flue gas stream. Consequently, deposition on surfaces of catalytic reactors occurs and rates of deposition are higher.
- 3) NOx reduction occurs on the flat surfaces of a catalyst and in pores within the flat surfaces. The pores are open to the flue gas passing through the catalyst reactor. Condensed vapors, alkali sulfates and alkaline-earth oxides and silicates are minute particles (less than 1 microns), which enter pores of the catalyst (a.k.a. plugging) and prevent catalytic reaction with NOx. Residual alkali vapors (Na, K, and Ca) displace hydrogen on fresh catalyst, which prevents catalytic reaction with NOx (a.k.a poisoning) and reacts with

²⁷ See, Benson, Steven A., Energy and Environmental Research Center, Ash Impacts on SCR Catalyst Performance, University of North Dakota, Grand Forks, ND.

²⁹ Id. at pg. 19.

³⁰ Findings and conclusions are summarized from the North Dakota Regional Haze SIP, Appendix B.5, pgs. 15-19.

³¹ Although the BART determination specifically references Fort Union lignite, the findings would apply to all North Dakota lignites.

sulfate to cause blinding of catalyst surfaces. Pore condensation of sodium also causes catalyst deactivation, which is a major deactivation mechanism. The rate of catalyst deactivation depends on the concentration and form of alkali in the flue gas; higher Na and K accelerate catalyst poisoning, blinding and plugging.

- 4) During the development of the initial planning period SIP, NDDEQ found that there were no SCR systems planned, constructed, or operating in the flue gas stream of boilers fired with North Dakota lignite. North Dakota lignite has certain coal characteristics that are uniquely different than Texas or Gulf Coast lignites, such as the larger proportion of organic matter and association of alkali, sodium specifically, with that organic matter.
- 5) Slipstream SCR reactors of the same design were installed at three power plants to test SCR for NO_x emissions control. One of the plants was cyclone fired with North Dakota lignite and the others with subbituminous coal. Deposition on the reactor surface after two months using the lignite was significantly greater; the deposits were rich in sodium, calcium, and sulfur. The tests confirmed catalyst blinding and plugging, but did not provide rates for catalyst deactivation. Tests also indicated that the deposits causing blinding and plugging of pores contained more sodium compared to PRB coal.

Based on a review of SCR installations on coal-fired boilers and a review of reported advances in SCR catalysts since the first planning period, deactivation rates due to soluble alkali compounds in the flue gas (including soluble sodium and potassium compounds) and the adhesive/cohesive characteristics and potential abrasive qualities of the North Dakota lignite-derived fly ash remain a concern for North Dakota lignite-fired boilers. SCR has not been installed and successfully operated on a North Dakota lignite-fired boiler, and the bench scale and pilot-scale studies needed to better understand ash behavior and catalyst blinding/erosion with North Dakota lignite-derived fly ash, and to better understand catalyst deactivation mechanisms associated with high soluble alkali compound concentrations in the flue gas have not been required or completed. Pilot-scale studies are needed to evaluate these issues to inform the development of advanced catalyst formulations, and to support the engineering and design studies needed to mitigate for potential deactivation routes (e.g., removing soluble alkali compounds from the flue gas and SCR design considerations such as catalyst formulation, catalyst pitch, reactor velocity, and catalyst surface and volume). Pilot-scale tests and engineering/design studies have not advanced since the first planning period's exhaustive analysis.

These issues have not been resolved since the first planning period and remain a significant barrier to the design and successful operation of high dust SCR on North Dakota lignite-fired boilers. The BART Guidelines state that "[a] control technique is considered available...if it has reached the stage of licensing and commercial availability."³² Commercial availability follows bench scale and laboratory testing and pilot scale testing. Consequently, the BART Guidelines state that "you would not consider technologies in the pilot scale testing stages

³² 40 CFR Part 51 Appendix Y, Section D.2.1.

of development as ‘available’ for purposes of BART review.”³³ Furthermore, source owners/operators are not expected to conduct extended trials to learn how to apply a technique on a dissimilar source type.³⁴ These BART guidelines also apply as a recommendation for the development of the LTS in the second planning period and the four factor analysis.³⁵ Because there are unresolved issues associated with catalyst poisoning, catalyst blinding and plugging, and catalyst erosion; and engineering solutions have not been determined or demonstrated and the high dust configuration has not moved beyond pilot scale testing, high dust SCR is not an available technically feasible NOx control technology for Coyote Unit 1.

Low-Dust Configuration

In the low-dust configuration, the SCR reactor vessel is located in the flue gas stream after the particulate collection device (i.e. ESP or FF). Employing this configuration would represent a relatively low level of exposure to fly ash (with the exception of submicron ash particles), but a potentially high level of vapor-phase alkalis, such as sodium. This configuration can be used on units equipped with particulate control only or units equipped with particulate control followed by a WFGD control system. The existing dry FGD/FF control configuration at Coyote Unit 1 for SO₂ and particulate control would preclude the application of a low-dust SCR configuration since, by definition, the SCR would have to be located downstream of both the dry FGD and FF. At that location the SCR would be more appropriately defined as a tail-end SCR configuration, which is described in more detail in the following section. Because Coyote Unit 1 is equipped with existing dry FGD/FF controls, low-dust SCR has no practical application on the unit, and low-dust SCR is not considered a technically feasible NOx control option for Coyote Unit 1.

Tail-End Configuration

In the tail-end configuration, the SCR reaction vessel is located in the flue gas stream after the particulate and FGD control systems. The potential advantage of a tail-end SCR configuration at Coyote Unit 1 is that the flue gas will have passed through the dry FGD/FF system prior to the SCR catalyst. As such, there is the possibility that the mass transfer mechanism that results in the capture of SO₂ will also capture some of the vapor-phase sodium and the sodium-enriched submicron particles, reducing the risk of catalyst poisoning and/or deactivation.

³³ Id.

³⁴ Id.

³⁵ See, Draft EPA Guidelines, pg. 183.

Successful operation of the tail-end configuration would also require a capital and operating cost-intensive gas-to-gas heat exchanger to reheat the flue gas from approximately 200 °F downstream of the existing FF to approximately 550°F to support the SCR NO_x reactions. After the flue gas passes through the SCR (at approximately 550°F), it would pass through the hot side of the gas-to-gas heat exchanger to cool the flue gas to 150°F prior to the exhaust stack. Although this stack gas temperature would be lower than the current stack temperature (190-210°F), it is still higher than the adiabatic saturation temperature of the flue gas (i.e., approximately 135°F). As such, it is likely that the existing stack could be reused without any major modifications.

During the first planning period, NDDEQ initially concluded, based on preliminary information provided by SCR catalyst vendors, that the tail-end SCR configuration would be a technically feasible option for units firing North Dakota lignite that are subject to BART requirements.³⁶ However, as part of the Milton R. Young Station (MRYS) NO_x BACT determination process, detailed information describing the expected ash characteristics and flue gas characteristics was provided to two SCR catalyst vendors (CERAM Environmental, Inc. (CERAM) and Haldor Topsoe, Inc.). Based on their review of the data, both vendors concluded that they would not be able to provide a catalyst life guarantee for either low-dust or tail-end SCR without pilot-scale testing.³⁷

Both vendors also made statements bringing into question the technical feasibility of either low-dust or tail-end SCR. For example, CERAM stated that the high levels of sodium oxide (Na₂O) in the ash for North Dakota lignite are not commonly found in subbituminous and bituminous coals which are fired in boilers equipped with SCR systems, and that it was unaware of any SCR application experience in the industry with the level and form of sodium in the North Dakota lignite-derived MRYS ash.³⁸

Based in part on this information provided by SCR design engineering firms and SCR catalyst vendors, NDDEQ concluded that the use of SCR technology, including low-dust and tail-end SCR, on the lignite-fired MRYS boilers would be technically infeasible.³⁹

Based on a review of SCR installations on coal-fired boilers, and a review of reported advances in SCR catalysts since the first planning period, deactivation rates due to soluble alkali compounds in the flue gas (including soluble sodium and potassium compounds) remain a concern for all North Dakota lignite-fired boilers. Tail-end SCR has not been demonstrated or installed on a North Dakota lignite-fired boiler, and there are still significant technical

³⁶ See, North Dakota Regional Haze State Implementation Plan for Regional Haze, February 24, 2010, Appendix B.5, pg. 25.

³⁸ *Id.*, at 1115-1116.

³⁹ *Id.*, at 1118.

concerns associated with the availability of existing SCR catalysts on a North Dakota lignite-fired unit. Catalyst in a tail-end SCR will still be vulnerable to alkali poisoning, pore pluggage, and premature catalyst deactivation, and it is not known whether the comparatively high levels of soluble sodium and potassium in North Dakota lignite will be effectively removed by the upstream dry FGD/FF. Furthermore, the potential exists for fine particulate remaining in the flue gas to get into the catalyst pores reducing catalyst activity. Pilot-scale studies needed to better understand catalyst deactivation mechanisms associated with high soluble alkali compound concentrations in the flue gas have not been completed.

In order to understand the effect of North Dakota lignite-derived flue gas on the tail-end SCR catalyst, identify potential design solutions, and evaluate the technical feasibility and effectiveness of tail-end SCR at Coyote Unit 1 with any degree of certainty, extended pilot scale testing of the control configuration would be needed. Additionally, because there are unresolved issues associated with catalyst poisoning, it's unlikely that OTP could obtain a viable commercial offering for tail-end SCR on Coyote Unit 1. Therefore, tail-end SCR is not an available technically feasible NOx control technology.

SCR Summary

During the first planning period NDDEQ determined that high-dust SCR and tail-end SCR are not available, and thus, not a technically feasible NOx control option for North Dakota lignite-fired boilers. The administrative record developed during the first planning period, including the BART determinations and MRYS BACT analysis, supports the conclusion that high-dust SCR and tail-end SCR are not an available NOx control option for Coyote Unit 1. An evaluation of SCR installations and reported advances in SCR catalysts since the first planning period, coupled with the fact that high-dust SCR and tail-end SCR have not been demonstrated on a North Dakota lignite-fired boiler, and the likelihood that OTP could not obtain a viable commercial offering for tail-end SCR without extended pilot-scale testing, continues to support the conclusion that high-dust SCR and tail-end SCR are not available NOx control technologies.

5.2.2.8 Technical Feasibility Summary

Table 5-10 summarizes the results of the feasibility evaluation of available control options for Coyote Unit 1.

Table 5-10. Technically Feasible NO_x Control Options

NO _x Control Option	Technically Feasible (Yes/No)	Technical Feasibility Summary
Combustion Optimization	Yes	Tuning to optimize the existing combustion system, including lower the stoichiometry in the cyclone barrels, tracking cyclone combustion stability, and adjusting the SOFA system (while staying within original OEM specifications) is a technically feasible NO _x control option.
Selective Non-Catalytic Reduction (SNCR)	Yes	SNCR is considered an available and technically feasible NO _x control technology for Coyote Unit 1. Computational fluid dynamic modeling and temperature mapping of the boiler would be needed to confirm that the incremental reduction in NO _x emissions is achievable without creating unacceptable operational issues.
Rich Reagent Injection (RRI)	No	RRI is considered an available and technically feasible NO _x control option cyclone burners at full load operation; however, at low load operation RRI does not provide effective NO _x control. Therefore, RRI alone is not considered an available NO _x control option, and will only be evaluated in conjunction with SNCR.
SNCR + RRI	Yes	Coupling RRI and SNCR is considered a technically feasible and commercially available NO _x control technology option on Coyote Unit 1. Computational fluid dynamic modeling and temperature mapping of the boiler would be needed to confirm that the incremental reduction in NO _x emissions is achievable without creating unacceptable operational issues.
Gas Reburn	No	The lack of natural gas availability at the Coyote Station precludes the ability to test and implement this control option on Coyote Unit 1. Therefore, gas reburn is not considered an available or technically feasible NO _x control technology at Coyote Unit 1.
Innovative Technologies: NOxStar™ PerNO _x ide LoTO _x Water Injection	No	Innovative NO _x control technologies are evaluated in Section 5.2.2.6. In all cases, the technologies have not been demonstrated on a large North Dakota lignite-fired boiler. Extensive testing and design engineering would be required to evaluate the technical feasibility and long-term effectiveness of each innovative control system on Coyote Unit 1. Therefore, the innovative NO _x control technologies are not considered available control options and are not technically feasible NO _x control options for Coyote Unit 1.
Selective Catalytic Reduction (SCR):		
High-dust configuration	No	Due to significant unresolved issues associated with catalyst poisoning, catalyst blinding and plugging, and catalyst erosion; and based on the finding that engineering solutions have not been determined or demonstrated and the high dust configuration has not moved beyond pilot scale testing, high dust SCR is not and available or technically feasible NO _x control technology for Coyote Unit 1.
Low-dust configuration	No	Because Coyote Unit 1 is equipped with existing dry FGD/FF

NO _x Control Option	Technically Feasible (Yes/No)	Technical Feasibility Summary
		control systems, low-dust SCR has no practical application on the unit, and low-dust SCR is not considered an available or technically feasible NO _x control option for Coyote Unit 1.
Tail-end configuration	No	Based on the continued lack of demonstration testing and commercial guarantees, tail-end SCR is not considered to be a technically feasible control option for Coyote Unit 1.

5.2.3 Evaluate Technically Feasible NO_x Control Options for Effectiveness

The technically feasible NO_x control technologies are listed in Table 5-11 in descending order of control efficiency. Table 5-11 also provides control option-specific NO_x emission rates in terms of lb/MMBtu. Emission rates shown in Table 5-11 represent average emission rates that the control options would be expected to achieve during normal operations.

Table 5-11. Evaluate Technically Feasible NO_x Control Options for Effectiveness

Control Technology	NO _x Emission Rate ^(Note 1) lb/MMBtu	% Reduction from Baseline Emission Rate
Baseline (existing SOFA)	0.46	-
SNCR + RRI + Combustion Optimization	0.20	56.2%
SNCR + Combustion Optimization	0.28	38.7%
Combustion Optimization	0.42	8.0%

Note 1. Emission rates shown in Table 5-11 represent average emission rates that the control options would be expected to achieve on an on-going long-term basis under normal operating conditions for Coyote Unit 1. Emission rates are provided for comparative purposes, and should not be construed to represent proposed emission limits. Corresponding permit limits must be evaluated on a control system-specific basis; an additional margin would likely be needed to account for operating margin. Additionally, for control options that include SNCR or RRI, computational fluid dynamic modeling and temperature mapping of the boiler would be needed to confirm that the incremental reduction in NO_x emission is achievable without creating unacceptable operational issues.

6. COSTS OF COMPLIANCE (STATUTORY FACTOR ONE)

The economic analysis performed as part of the Four Factor analysis examines the cost-effectiveness of each technically feasible control technology, on a dollar per ton of pollutant removed basis. Annual emissions, calculated for a particular control device, are subtracted from baseline annual emissions to calculate tons of pollutant controlled per year. For units with existing controls, the base case represents existing baseline actual emissions. Annual costs for each control option are calculated relative to the base case by adding annual operation and maintenance (O&M) costs to the annualized cost of capital and, if applicable, lost revenue due to extended outage required for installation of control equipment. Capital costs and lost revenues were annualized using a capital recovery factor based on an annual interest rate of 5.25%⁴¹ and equipment life of 20 years.⁴² Cost effectiveness (\$/ton) of a particular control option is simply the annual cost (\$/yr) divided by the annual reduction in annual emissions (ton/yr). In addition to cost-effectiveness relative to the base case, the incremental cost-effectiveness to go from one level of control to the next, more stringent, level of control may also be calculated to evaluate the incremental cost effectiveness of the more stringent control.

Capital and O&M cost estimates were developed for each of the technically feasible SO₂ and NO_x control options. The Coyote Unit 1 cost estimates are conceptual in nature; thus, S&L did not procure equipment quotes specifically for the Unit 1 control system upgrades. Rather, equipment costs are based on conceptual designs developed for the retrofit control systems, preliminary equipment sizing developed for the major pieces of equipment (based on Coyote Unit 1-specific design parameters, including typical fuel characteristics, full load heat input, and flue gas temperatures and flow rates), and recent pricing for similar equipment. S&L would characterize the cost estimates for the Coyote Unit 1 retrofit technologies as “concept screening” cost estimates generally based on parametric models, judgment, or analogy.

⁴¹ In an email to the North Dakota Department of Health dated December 18, 2018, EPA recommended use of a 5.25% interest rate. Otter Tail does not necessarily agree that this is an appropriate percentage to use and reserves the right to update and modify this percentage at a later date. Notably, on September 26, 2018 the North Dakota Public Service Commission approved a rate of return for Otter Tail of 7.64% (See <https://psc.nd.gov/database/documents/17-0398/226-020.pdf>). This ROR represents a total weighted average cost of capital. An interest rate of 5.25% is more representative of the long-term cost of debt, which is only one component of capital structure.

⁴² The assumed 20-year equipment life is consistent with the control system equipment life used by NDDEQ in its evaluation of NO_x and SO₂ control technologies for BART-eligible sources. (see, e.g., ND Regional Haze Final SIP, Appendix C.1, “BART Determination Study for Leland Olds Station Units 1 & 2, Basin Electric Power Cooperative, August 2006, pgs. 64 (NO_x controls) and 158 (SO₂ controls). See also, ND Regional Haze Final SIP, Appendix C4, “NO_x Best Available Control Technology Study for Milton R. Young Station Unit 1, Minnkota Power Cooperative, Inc., October 2006, pg. 3-22).

Control technology equipment costs for the retrofit options were developed by scaling cost estimates prepared by S&L for other similar projects. Major equipment costs were developed based on equipment costs recently developed for similar projects, and include the equipment, material, labor, and all other direct costs needed to retrofit the units with the control technology. Sub-accounts for the capital cost estimates (e.g., mobilization and demobilization, consumables, Contractor G&A expense, freight on materials, etc.) were developed by applying ratios from detailed cost estimates that were prepared for projects with similar scopes.

Fixed O&M costs include operating labor, maintenance labor, maintenance material, and administrative labor. Variable O&M costs include the cost of consumables, including reagent, water consumption, and auxiliary power requirements.⁴³ Auxiliary power requirements reflect the additional power requirements associated with the operation of the new control technology (compared to the existing technology). All O&M costs reflect the incremental increase in O&M costs compared to the costs incurred to operate the existing dry scrubber and FF control systems.

In addition to the cost effectiveness relative to the base case, the incremental cost-effectiveness to go from one level of control to the next more stringent level of control will also be calculated to evaluate the cost effectiveness of the more stringent control.

The results of the SO₂ and NO_x control cost evaluations are included below in Sections 6.1 and 6.2.

6.1 ECONOMIC EVALUATION – SO₂ CONTROLS

Table 6-1 presents the capital costs and annual operating costs associated with installing and operating each technically feasible SO₂ control system for Unit 1. Table 6-2 shows the average annual and incremental cost effectiveness for each control system. Additional cost details are provided in Appendix B.

Cost estimates were not prepared for the SDA/FF option since the capital and operating costs for the SDA/FF option would be similar to the costs for the CDS/FF option, and the CDS/FF option would likely provide the opportunity to achieve somewhat lower controlled SO₂ emissions (compared to SDA/FF). Therefore, of the two new DFGD system options, only the CDS/FF option was evaluated.

⁴³ Variable O&M costs are based on an uncontrolled SO₂ of 2.3 lb/MMBtu as recommended by the NDDEQ.

Table 6-1. SO₂ Control Cost Summary (\$2018)

SO ₂ Control Option	Total Capital Investment \$	Annualized Capital Cost \$/yr	Annual Operating Cost \$/yr	Total Annual Cost \$/yr
DSI + Existing FGD	\$23,765,000	\$1,948,000	\$10,423,000	\$12,371,000
FGD Operational Improvements – Increase Ca:S Stoichiometric Ratio	\$526,000	\$43,000	\$2,042,000	\$2,085,000
DSI + FGD Operational Improvements	\$24,292,000	\$1,991,000	\$12,465,000	\$14,456,000
FGD Upgrades - Replacing Existing Absorbers with New Absorber	\$127,823,000	\$10,475,000	\$6,332,000	\$22,197,000 ^(Note 1)
Dry FGD (CDS) + Existing FF	\$242,647,000	\$19,885,000	\$20,610,000	\$40,495,000
Wet FGD	\$324,742,000	\$26,613,000	\$22,481,000	\$49,094,000

Note 1. Total annual cost for “FGD Upgrades - Replacing Existing Absorbers with New Absorber” option includes annualized lost revenue due to extended outage and replacement power required for installation (\$5,390,000).

Table 6-2. SO₂ Emissions Control System Cost Effectiveness (\$2018)

SO ₂ Control Option	Total Annual Cost \$/yr	Expected Emission Reduction tons SO ₂ /yr	Average Annual Cost Effectiveness (Note 1) \$/ton SO ₂ removed	Incremental Annual Cost Effectiveness (Note 2, 3) \$/ton SO ₂ removed
Baseline (Existing DFGD/FF)	---	---	---	---
DSI + Existing FGD	\$12,371,000	4,131	\$2,994	
FGD Operational Improvements – Increase Ca:S Stoichiometric Ratio	\$2,085,000	5,354	\$389	n/a
DSI + FGD Operational Improvements	\$14,456,000	7,952	\$1,818	\$4,762
FGD Upgrades - Replacing Existing Absorbers with New Absorber	\$22,197,000	8,563	\$2,592	\$12,664
Dry FGD (CDS) + Existing FF	\$40,495,000	11,619	\$3,485	\$5,987
Wet FGD	\$49,094,000	12,078	\$4,065	\$18,757

Note 1. Average cost effectiveness for each control option is the total annual cost divided by the expected emission reduction.

Note 2. Incremental cost effectiveness represents the incremental increase in annual costs (\$/yr) divided by the incremental increase in annual emissions reductions (tpy) between a control option and the next most effective option.

Note 3. "n/a" indicates that the next most effective control option is "inferior" (i.e., higher cost for less control)

Table 6-2 indicates that the average annual cost effectiveness of the technically feasible SO₂ control options for Unit 1 range from \$389 per ton (FGD Operation Improvements) to \$4,065 per ton (Wet FGD). Costs associated with equipment procurement and installation, and annual operating costs all have a significant impact on the cost of the SO₂ control systems.

Annual costs of the DSI system exceed the costs of the FGD Operational Improvements option, and the DSI system achieves lower SO₂ reductions. Therefore, the DSI system is an "inferior" control option.

The FGD Operational Improvements option would require the relatively low capital investment for upgrading the existing atomizer wheel and an increase in operating costs primarily due to increased reagent usage. This option will achieve approximately 41% SO₂ reduction from the baseline levels, resulting in a cost effectiveness of \$465 per ton.

The option to incorporate FGD Operational Improvements and install a DSI system will achieve approximately 61% SO₂ reduction from the baseline. Capital costs are primarily attributed to the DSI equipment, and high operating costs are due to a significant increase in hydrated lime use. The cost effectiveness of the DSI + FGD Operational Improvements option is \$1,818 per ton. Comparing this option to the next most effective control option, FGD Operational Improvements (without DSI), the incremental costs effectiveness is \$4,762 per ton.

Replacing the existing absorber modules with new absorber modules will require Coyote Unit 1 to be taken off-line for approximately 12 months. In addition to capital and operating costs, the Coyote Station will incur costs associated with lost production and purchase of replacement power. The cost effectiveness of the FGD Upgrade - Replacing Existing Absorbers with New Absorber option is \$2,592 per ton. Comparing this option to the next most effective control option, DSI + FGD Operational Improvements, the incremental cost effectiveness is \$12,664 per ton.

The installation of new Dry FGD (CDS) or new Wet FGD systems are high capital and annual operating cost options. The cost effectiveness for these options are \$3,485 per ton (Dry FGD) and \$4,065 per ton (Wet FGD). The incremental cost of installing a Dry FGD system, compared to FGD Upgrades, is \$5,987 per ton. The incremental cost of installing a Wet FGD system, compared to a Dry FGD system, is \$18,757 per ton.

6.2 ECONOMIC EVALUATION – NO_x CONTROLS

Table 6-3 presents the capital costs and annual operating costs associated with building and operating each control system. Table 6-4 shows the average annual and incremental cost effectiveness for each control system. Additional cost details are provided in Appendix C.

Table 6-3. NO_x Control Cost Summary (\$2018)

NO _x Control Option	Total Capital Investment \$	Annual Capital Cost \$/yr	Annual Operating Cost \$/yr	Total Annual Cost \$/yr
Combustion Optimization	\$0	\$0	\$0	\$0
SNCR + Combustion Optimization	\$19,840,000	\$1,626,000	\$3,128,000	\$4,754,000
SNCR + RRI + Combustion Optimization	\$25,895,000	\$2,122,000	\$6,495,000	\$8,617,000

Table 6-4. NO_x Emissions Control System Cost Effectiveness (\$2018)

NO _x Control Option	Total Annual Cost \$/yr	Expected Emission Reduction tons NO _x /yr	Average Annual Cost Effectiveness (Note 1) \$/ton NO _x removed	Incremental Annual Cost Effectiveness (Note 2) \$/ton NO _x removed
Baseline (Existing SOFA)	---	---	---	---
Combustion Optimization	\$0	589	\$0	\$0
SNCR + Combustion Optimization	\$4,754,000	2,847	\$1,670	\$2,105
SNCR + RRI + Combustion Optimization	\$8,617,000	4,137	\$2,083	\$2,994

Note 1. Average cost effectiveness for each control option is the total annual cost divided by the expected emission reduction.

Note 2. Incremental cost effectiveness represents the incremental increase in annual costs (\$/yr) divided by the incremental increase in annual emissions reductions (tpy) between a control option and the next most effective option.

Table 6-4 indicates that the average annual cost effectiveness of the technically feasible NO_x control options for Unit 1 range from \$0 per ton (Combustion Optimization) to \$2,083 per ton (SNCR + RRI) NO_x removed.

The Combustion Optimization option is expected to achieve 8% NO_x reduction from baseline levels without impact to boiler performance. This option can be implemented without additional capital or operating costs; therefore, the cost effectiveness is \$0 per ton.

Installation of an SNCR system is expected to achieve approximately 39% NO_x reduction. The cost effectiveness of this option is \$1,670 per ton. Compared the next most effective option, Combustion Optimization, the incremental cost effectiveness is \$2,105 per ton.

The option to install an SNCR system combined with RRI would achieve approximately 56% NO_x reduction. Compared to installing SNCR alone, this option incurs additional capital costs for the RRI system and higher operating costs primarily due to increased urea consumption. The cost effectiveness of the SNCR + RRI option is \$2,083 per ton, and the incremental cost compared to SNCR alone is \$2,994 per ton.

7. TIME NECESSARY FOR COMPLIANCE (STATUTORY FACTOR TWO)

The time necessary for compliance is generally defined as the time needed for full implementation of the technically feasible control options. This includes the time needed to develop and implement the regulations, as well as the time needed to install the selected control equipment. The time needed to install the control equipment includes time for equipment procurement, design, fabrication, and installation. If reasonable progress measures are required at Coyote Station for the Regional Haze second planning period, the anticipated compliance deadline would be July 1, 2028.⁴⁴ However, this compliance deadline must provide a reasonable amount of time for the source to implement the control measure.

Table 7-1 and Table 7-2 include estimated timeframes needed to implement each of the technically feasible control options. Notably, the estimated timeframes do not account for time needed for North Dakota to develop and implement the regulations; nor the amount of time needed for EPA to take proposed and final action to approve North Dakota's SIP.

⁴⁴ For the first planning period, on March 14, 2011 the North Dakota Department of Health issued permit to construct number PTC10008 that required Coyote Station to meet the approved reasonable progress limitation by July 1, 2018.

Table 7-1. SO₂ Emissions Control System Implementation Schedule

SO ₂ Control Option	Design / Specification / Procurement (months)	Detail Design / Fabrication (months)	Construction / Commissioning / Startup (months)	Total (months after SIP approval)
DSI + Existing FGD	6	6	6	18
FGD Operational Improvements – Increase Ca:S Stoichiometric Ratio	0	0	0	0
DSI + FGD Operational Improvements	6	6	6	18
FGD Upgrades - Replacing Existing Absorbers with New Absorber	8	12	12	32
Dry FGD (CDS) + Existing FF	12	20	18	50
Wet FGD	12	22	22	56

Table 7-2. NO_x Emissions Control System Implementation Schedule

NO _x Control Option	Design / Specification / Procurement (months)	Detail Design / Fabrication (months)	Construction / Commissioning / Startup (months)	Total (months after SIP approval)
Combustion Optimization	0	0	0	0
SNCR + Combustion Optimization	10	6	6	22
SNCR + RRI + Combustion Optimization	10	6	6	22

8. ENERGY AND NON-AIR QUALITY ENVIRONMENTAL IMPACTS (STATUTORY FACTOR THREE)

The primary purpose of the environmental impact analysis is to assess collateral environmental impacts due to control of the regulated pollutant in question. Environmental impacts may include solid or hazardous waste generation, discharges of polluted water from a control device, visibility impacts, increased emissions of other criteria or non-criteria pollutants, increased water consumption, and land use impacts from waste disposal.

8.1 ENVIRONMENTAL IMPACTS

Coyote Unit 1 is currently equipped with SOFA for NO_x control and dry scrubber technology for SO₂ control. The hydrated lime reactant used in a dry scrubbing system reacts with SO₂ in the flue gas to form calcium sulfate and calcium sulfite solids. The solids are captured in the existing FF particulate control system and either returned to the system for reuse or removed from the system as nonhazardous solid waste. The existing dry scrubbing system also requires water to hydrate the lime prior to injection into the reaction modules. Based on the design of the control system, Coyote Unit 1 currently uses approximately 465 gpm of water to hydrate the lime (at full load). Collateral environmental impacts associated with the existing Coyote Unit 1 control systems include water consumption and increased solid waste generation. There were no collateral impacts associated with the SOFA system.

Based on a review of potential non-air quality environmental impacts, no significant collateral environmental impacts were identified for any of the SO₂ and NO_x control options included in this evaluation, with the exception, potentially, of the WFGD, DSI, and SNCR/RRI options. No significant non-air quality environmental impacts were identified for the options that include replacing the existing scrubber modules with new scrubber modules, FGD operational improvements/upgrades or combustion optimization. Collateral environmental impact identified for the sorbent injection control option includes an increase in the solid waste generation. The sorbent injection system will increase the solid waste generated by approximately 50% (47,000 lb/hr to 70,000 lb/hr).

There are a number of potential non-air quality environmental impacts associated with the WFGD control option. Unlike dry scrubbing systems that generate a dry FGD byproduct, WFGD systems generate a liquid calcium sulfate by-product that must be dewatered prior to disposal. WFGD control systems can be designed with forced oxidation that results in a gypsum-grade by-product that can be sold into the local gypsum market. If an adequate gypsum

market is not available, the gypsum by-product will require disposal. WFGD control systems also generate a wastewater stream that must be treated prior to discharge. WFGD wastewaters typically consist of a saturated solution of calcium sulfate, calcium sulfite, and sodium chloride, with trace amounts of fly ash and unreacted limestone. Traces of metal ions may also be present due to fly ash carryover from the flue gas to the WFGD scrubber liquor. WFGD wastewater treatment systems typically require calcium sulfate/sulfite desaturation, heavy metals precipitation, coagulation/precipitation, and sludge dewatering. Treated wastewater is typically discharged to surface water pursuant to an NPDES discharge permit, and solids are typically disposed of in a landfill.

WFGD systems also require significantly more water than the dry systems. Based on design criteria for wet and dry FGD control systems, WFGD systems typically require approximately 25-30% more water than a similarly sized DFGD control system. This would increase water consumption at Coyote Unit 1 on average approximately 130 gpm. Water consumption is an important factor when assessing potential non-air quality environmental impacts at facilities located in North Dakota, and could represent a significant non-air quality collateral environmental impact.

In addition, the SNCR and SNCR/RRR control options have the collateral impact of ammonia slip emissions at 10 ppm since these options utilize ammonia as the reagent for the reactions with NO_x to occur. Ammonia slip emissions from the SNCR/RRR options will likely end up in the dry FGD solids.

8.2 ENERGY IMPACTS

Options that include replacing the existing Unit 1 dry scrubbing system with a CDS/FF or WFGD system will increase pressure drop through the control systems, increase auxiliary power requirements, and adversely affect the unit's net plant heat rate (Btu heat input per MW_{Net} output).⁴⁵ Consequently, heat input to the boiler would need to increase to compensate for the increased auxiliary power requirements while achieving the same net plant output, or net output from the unit would decrease.

Although several of the control options have energy impacts, none of the impacts are considered significant enough as to disqualify any of the options from consideration in the four factor analysis. In order to account for potential energy impacts associated with each option, the auxiliary power cost associated with operating the control systems have been included as an annual operating cost in the economic impact assessment.

⁴⁵ Heat rate represents the amount of heat input to the boiler (Btu) required to generate one megawatt (MW) net electric output and is reported as Btu/MW_{Net}.

8.3 ENVIRONMENTAL / ENERGY IMPACTS SUMMARY

A summary of the environmental and energy impact analysis is provided in Table 8-1.

Table 8-1. Summary of Energy and Non-Air Quality Environmental Impacts

Control Option	Collateral Environmental & Energy Impacts
Baseline	<ul style="list-style-type: none"> ➤ Coyote Unit 1 is currently equipped with dry scrubbing / FF control systems. Existing collateral environmental and energy impacts include: ➤ Solid FGD by-product management and disposal ➤ Increased water consumption ➤ Increased auxiliary power requirements and heat rate penalty
<u>SO₂ Control Options</u>	
Replace existing DFGD with New WFGD control system	<ul style="list-style-type: none"> ➤ Increased water consumption ➤ Wet by-product that requires dewatering prior to disposal ➤ FGD wastewater treatment & discharge ➤ Increased auxiliary power requirements and heat rate penalty
Replace existing DFGD with New CDS/FF Control System	<ul style="list-style-type: none"> ➤ Increased auxiliary power requirements and heat rate penalty ➤ Increased solid FGD by-product management and disposal
Replace existing dry scrubber modules with New DFGD modules while keeping existing FF	<ul style="list-style-type: none"> ➤ Requires extended (approximately 12-month) outage of Coyote Unit 1 to demolish and replace the existing scrubber modules
Dry Sorbent Injection	<ul style="list-style-type: none"> ➤ Increased solid FGD by-product management and disposal ➤ Increased auxiliary power requirements and heat rate penalty
<u>NO_x Control Options</u>	
SNCR or SNCR + RRI	<ul style="list-style-type: none"> ➤ Increased ammonia slip emissions ➤ Increased auxiliary power requirements and heat rate penalty

9. REMAINING USEFUL LIFE (STATUTORY FACTOR FOUR)

The evaluation of technically feasible NO_x and SO₂ controls options should consider the source's "remaining useful life" in determining the costs of compliance. The remaining useful life is the difference between the date that controls would be put in place and the date that the facility permanently ceases operation. If the remaining useful life of the unit is shorter than the useful life of a particular control option, the remaining useful life should be used to annualize costs. If the remaining useful life exceeds the useful life of the control options, the remaining use life has no effect on the cost evaluation.

The cost of compliance for each control option (see Section 6) currently calculates the annual capital recovery cost by multiplying the total capital investment by a CRF from a formula based on a 20-year equipment lifetime. The Coyote Station owners have not identified dates for the remaining useful life of the unit before the end of what would otherwise be the useful life of the control measures that were evaluated for Coyote Unit 1. Thus, the 20-year equipment life of the control measures was used in the four factor analysis to calculate emission reductions, amortized costs, and cost-effectiveness.

10. FOUR-FACTOR ANALYSIS SUMMARY

At the request of NDDEQ, a four factor analysis was prepared for Coyote Unit 1. The analysis identified technically feasible SO₂ and NO_x control options for Unit 1, and evaluated each of the control measures for the following four statutory factors:

1. The costs of compliance;
2. The time necessary for compliance;
3. The energy and non-air quality environmental impacts of compliance; and
4. The remaining useful life of any potentially affected anthropogenic source of visibility impairment.

The cost of compliance evaluation prepared for SO₂ controls indicates that the average annual cost effectiveness ranges from \$389 per ton (FGD Operation Improvements) to \$4,065 per ton (Wet FGD). The evaluation prepared for NO_x controls options indicates that the average annual cost effectiveness ranges from \$0 per ton (Combustion Optimization) to \$2,083 per ton (SNCR + RRI) NO_x removed.

The time necessary for compliance for the SO₂ control options ranges from 0 months (FGD operational improvements) to 56 months (new wet FGD system). For NO_x control options, the time necessary for compliance ranges from 0 months (combustion optimization) to 22 months (SNCR + RRI).

An evaluation of energy impacts indicates that certain control options (e.g., new FGD systems) will increase auxiliary power requirements due to increased pressure drop, which would adversely impact net plant heat rate. Consequently, heat input to the boiler would need to increase to compensate for the increased auxiliary power requirements while achieving the same net plant output, or net output from the unit would decrease. Collateral environmental impacts include an increase in the solid waste generation with DSI, as well as potential incremental increase in fugitive dust emissions associated with sorbent deliveries to the facility.

Regarding remaining useful life, the Coyote Station owners have not identified dates for the remaining useful life of the unit before the end of what would otherwise be the 20-year useful life of the control measures that were evaluated for Coyote Unit 1. Therefore, the remaining useful life did not impact the annualized cost of control under the current regulatory framework.

Mr. Jim Semerad
Director, Division of Air Quality
North Dakota Department of Health
Gold Seal Center, 918 East Divide Ave
Bismarck, ND 58501-1947

Dear Mr. Semerad:

Re: Updates to Regional Haze Four Factor Analysis - Coyote Station

The purpose of this submittal is to provide the North Dakota Department of Environmental Quality (DEQ) with updated information related to the NOx technology options presented in the Coyote Station Regional Haze reasonable progress report (Four-Factor Analysis).

As you recall, Revision 1 of the Four-Factor Analysis, dated May 8, 2019, determined that there were two technically feasible post-combustion NOx technologies applicable to Coyote Station: Selective non-catalytic reduction (SNCR) and Rich Reagent Injection (RRI). The Four-Factor Analysis presented the predicted emission reductions and costs associated with those technologies; however, in both cases the report noted that computational fluid dynamic (CFD) modeling would be needed to confirm that the incremental reduction in NOx emission is achievable without creating unacceptable operational issues.¹

Subsequent to the Four-Factor Analysis, Otter Tail Power Company proceeded with the CFD modeling, and retained Sargent & Lundy, L.L.C. (S&L) to prepare the attached technical memorandum to summarize the modeling results and determine the associated impacts to the Four-Factor Analysis.

As described in the S&L memorandum, it has been determined that in order to achieve the level of NOx reductions with RRI originally predicted by the Four-Factor Analysis, Coyote Station would need to relocate both the existing furnace vent ports and separated overfire air ports. Therefore, the costs of the RRI option need to be revised upward to account for these port relocations.

We look forward to working with the DEQ throughout the second planning period. If you have any questions about this updated information, please contact me at (218) 739-8526.

Sincerely,

Mark Thoma
Manager, Environmental Services

Enclosure

TECHNICAL MEMORANDUM

From: Wayshalee Patel
Date: January 6, 2020
Project No.: A12715.011

Client: Otter Tail Power Company
Station: Coyote Station Unit 1

Subject: Update to Four Factor Analysis

The purpose of this technical memorandum is to provide the North Dakota Department of Environmental Quality (NDDEQ) a summary of computational fluid dynamic (CFD) modeling recently completed by Otter Tail Power Company (OTP) since the submittal of the Coyote Station Unit 1 Four-Factor Analysis dated May 8, 2019. For nitrogen oxides (NO_x), the CFD modeling was conducted for the selective non-catalytic reduction (SNCR) and rich reagent injection (RRI) technology options.

NO_x CFD Modeling Summary

OTP engaged Reaction Engineering International (REI) to complete CFD modeling of OTP's Coyote Station Unit 1 to further evaluate and potentially refine the emission removal capabilities and equipment modifications necessary for SNCR and RRI for NO_x emissions.

NO_x Emissions Modeling:

REI developed a CFD model of the Coyote Unit 1 cyclone barrels and boiler furnace in order to evaluate the impact of various technologies on Unit 1 furnace NO_x reduction. The modeling effort assessed performance of combustion modifications, SNCR, and RRI systems and generally evaluated the following:

- SNCR with sensitivity to injector locations, urea solution droplet sizes, and normalized stoichiometric ratio (NSR)
- RRI exploring injector locations and performance when combined with existing and alternative OFA and vent designs

The results of the NO_x CFD modeling effort predict that the average NO_x emission rate achievable with SNCR is 0.28 lb/MMBtu¹, which is the value that was estimated in the Four-Factor Analysis. As such, the achievable emission reduction and associated costs and cost effectiveness for SNCR provided in the Four-Factor Analysis is reasonable and updates are not necessary. For the RRI option, the CFD modeling

¹ Modeling scenarios that resulted in a predicted ammonia slip of greater than 10 ppm were not included in determining this average in order to avoid formation of ammonia salts on the boiler tube banks.

indicated that the 12 existing furnace vents and the 14 existing separated overfire air (SOFA) vents would need to be relocated at an elevation higher in the furnace in order to create sub-stoichiometric oxygen concentrations in the lower furnace, thereby promoting NO_x reduction. The Four-Factor Analysis did not include the costs associated with relocating these SOFA and vent ports which, based on the CFD modeling, is necessary to obtain the estimated NO_x reductions indicated in the Four-Factor Analysis. As such, the cost effectiveness table provided in the Four-Factor Analysis has been updated and is provided in Table 1 below. In summary, the cost effectiveness for the option that included RRI increased from \$2,083/ton to \$3,067/ton. Detailed cost effectiveness tables are included in Appendix A of this memorandum.

Table 1. NO_x Emissions Control System Cost Effectiveness (\$2018)

	Total Annualized Cost	Expected Emission Reduction	Average Annual Cost Effectiveness (Note 1)	Incremental Annual Cost Effectiveness (Note 2)
NO_x Control Option	\$/yr	tons NO_x/yr	\$/ton NO_x removed	\$/ton NO_x removed
Baseline (Existing SOFA)	---	---	---	---
Combustion Optimization	\$0	589	\$0	\$0
SNCR + Combustion Optimization	\$4,754,000	2,847	\$1,670	\$2,105
SNCR + RRI + Combustion Optimization + SOFA/Vent Port	\$12,690,000	4,137	\$3,067	\$6,150

Note 1. Average cost effectiveness for each control option is the total annual cost divided by the expected emission reduction

Note 2. Incremental cost effectiveness represents the incremental increase in annual costs (\$/yr) divided by the incremental increase in annual emissions reductions (tpy) between a control option and the next most effective option.

TECHNICAL MEMORANDUM

Mr. James L. Semerad
Director, Division of Air Quality
North Dakota Department of Health
Gold Seal Center, 918 East Divide Ave
Bismarck, ND 58501-1947

Dear Mr. Semerad:

Re: Update to Regional Haze Four Factor Analysis - Coyote Station

The purpose of this submittal is to provide the North Dakota Department of Environmental Quality (DEQ) with updated information related to the sulfur dioxide (SO₂) technology options presented in the Coyote Station Regional Haze Four-Factor Analysis.

As you may recall, Revision 1 of the Four-Factor Analysis, dated May 8, 2019, determined that there were six technically feasible SO₂ technologies applicable to Coyote Station. One of these options involved retrofitting the existing dry flue gas desulfurization (DFGD) system with a new absorber module(s). This option was specifically limited to dismantling Coyote Station Unit 1's existing absorber modules and installing a new reactor absorber(s) in the same location. The same location was used for the retrofit absorbers as the existing DFGD because, at the time of the initial Four-Factor Analysis, it was predicted that redirecting flue gas to a different location would likely result in significant solids dropout and other operational issues.¹

Subsequent to the Four-Factor Analysis, Otter Tail Power Company (OTP) became aware of a recent successful project by Babcock and Wilcox (B&W) that involved redirecting flue gas to a new SDA module located adjacent to an existing fabric filter. Therefore, OTP engaged B&W and Sargent & Lundy, L.L.C. (S&L) to perform a supplemental evaluation of this option for Coyote Station Unit 1. The attached technical memorandum from S&L summarizes the results of that evaluation and associated impacts to the Four-Factor Analysis.

We look forward to working with the DEQ throughout the second planning period. If you have any questions about this updated information, please contact me at (218) 739-8526.

Sincerely,

A handwritten signature in black ink that reads "Mark Thoma".

Mark Thoma
Manager, Environmental Services

From: Wayshalee Patel

Date: June 4, 2020

Project No.: A12715.011

Client: Otter Tail Power Company

Station: Coyote Station Unit 1

Subject: Update to Four Factor Analysis

The purpose of this technical memorandum is to provide the North Dakota Department of Environmental Quality (NDDEQ) a summary of an additional evaluation regarding replacement of the existing spray dry absorber (SDA) modules with new absorber module(s) on the Otter Tail Power Company (OTP) Coyote Station Unit 1.

SDA Module Replacement Option

One of the technically feasible sulfur dioxide control technologies presented to the NDDEQ in the initial Four-Factor Analysis for Coyote Station Unit 1 involved retrofitting the existing dry flue gas desulfurization (DFGD) system with a new absorber modules.¹ This option was specifically limited to dismantling Coyote Station Unit 1's existing absorber modules and installing new reactor absorbers in the same location. The same location was used for the retrofit absorbers as the existing DFGD because, at the time of the initial Four-Factor Analysis, it was predicted that redirecting flue gas to a different location would likely result in significant solids dropout and other operational issues.

Since submittal of the Four-Factor Analysis, OTP became aware of a recent successful project by Babcock and Wilcox (B&W) that involved redirecting flue gas to a new SDA module located adjacent to an existing fabric filter.² Therefore, OTP engaged B&W and Sargent & Lundy to perform a supplemental evaluation of this option for Coyote Station Unit 1.

B&W evaluated single module and two-module equipment arrangements for Coyote Station Unit 1. Given B&W's extensive project experience and Coyote Station's operating conditions, B&W's evaluation focused on the two-module design in order to confidently treat 100% of the Coyote Station Unit 1 flue gas. B&W's evaluation determined that Coyote Station's flue gas could in fact be re-directed through two new 62 ft. diameter modules³ located adjacent to the existing Coyote Station Unit 1 DFGD, and then following the new SDA modules, the flue gas could be routed back to the existing Reverse Air Fabric Filter (RAFF). The

¹ See *Coyote Station Unit 1: North Dakota Regional Haze Second Planning Period Four-Factor Analysis*. May 8, 2019.

² In 2017, B&W installed a new SDA adjacent to an existing fabric filter at the Colorado Springs Utilities Nixon Plant.

³ These exact modules have been installed by B&W at several sites, and most recently at Alliant Columbia Power Station (start-up 2015).

expected performance of this arrangement is an average controlled SO₂ emission rate of approximately 0.09 lb/MMBtu at Coyote Station Unit 1.

Balance of Plant Impacts

The following balance of plant systems were evaluated by Sargent & Lundy to determine what other modifications to the existing systems would be required as part of the overall retrofit cost for the B&W two absorber module option.

Pebble Lime Reagent Preparation & Fresh Lime Slurry System:

- The storage duration of the existing lime silo (63,000 ft³ or 1,733 tons) will be reduced from over 15.75 days of storage to 5.89 days assuming the unit is operated at full load, 100% capacity. This would result in an increased number of pebble lime deliveries; however no modifications will be required for the storage silos.
- The existing detention slakers and the rest of the slaking equipment will be reused; no modifications required. However, a new slaker water flow control valve (FCV) will be added to increase the controllable flow up to 375 gpm.
- The existing reagent mix tank reagent feed pumps (150 gpm) are undersized and will be replaced with new 2 x 100% lime slurry transfer pumps (500 gpm).
- The two (2) existing atomizer feed tanks (11,800 gal) will be repurposed as the lime slurry feed tanks, new 2 x 100% lime slurry feed pumps will transfer slurry to new 2 x 50% atomizer head tanks located in the new SDA penthouse. The lime slurry will be fed to the atomizer head tank in a continuous loop returning to the lime slurry storage tank. Flow from the continuous loop will be metered into the atomizer head tank based on unit load, inlet SO₂, the SO₂ emission setpoint and trimmed by the SO₂ feedback measured at the stack.

Recycle Slurry System:

- Solids from the existing RAFF are collected and transported (via the ash handling system) to the existing recycle silo (38,000 ft³). No modifications required.
- A new rotary feeder will be added at the outlet of the recycle silo to meter recycle solids into the recycle mixer where water will be added to achieve an increased recycle slurry solids content of 45% solids.
- New 2 x 100% fly ash slurry transfer pumps will forward slurry to the existing reagent storage tanks that will be repurposed as recycle slurry storage tanks.
- The recycle mix chamber agitator, recycle fly ash wetting tank agitator and the repurposed recycle slurry tank agitators will be upgraded and/or replaced to handle the increase in torque caused by the higher recycle slurry solids content.
- The existing 2 x 100% recycle slurry feed pumps will be upgraded to be capable of transferring the new slurry demand. Similar to the new lime slurry feed pumps, the recycle slurry will be fed in a continuous loop to the new atomizer head tanks to maintain a tank level setpoint.

Byproduct/Waste Ash Conveying System:

- Sargent & Lundy evaluated the original design of the existing waste ash conveying system and determined that the existing system is sufficiently sized to operate with the higher byproduct generation.

Waste Ash Silo:

- When operating to achieve an outlet SO₂ emission of 0.09 lb/MMBtu, the produced waste ash will have a higher concentration of FGD byproducts and unreacted lime, and therefore a decreased concentration of fly ash which will decrease volumetric density of the waste ash.
 - Based on the original waste ash silo design information available, Sargent & Lundy estimated approximately six days (147 hours) of storage, assuming the unit is operated at full load, 100% capacity.
 - With the higher concentration of FGD byproducts and unreacted lime, the waste ash density was estimated to be reduced to approximately 34 lb/ft³ (reduced fly ash concentration ~29%), reducing the storage duration to a little over three days (85 hours), assuming the unit is operated at full load, 100% capacity.
 - As 3 days of storage is typically recommended as the minimum storage time to cover operation over long weekends without silo unloading activities, it is assumed that the plant should still be able to manage loadout activities accordingly, and therefore no modifications or new equipment is required.
- The unloader from the silo is sufficiently rated and should not require any modifications.
- The waste ash is conditioned with water in pug mills for truck unloading. The plant has made recent upgrades to the water spray headers to the pug mills and have adequate water to condition the increased amount of waste ash loadout activities.
- To help facilitate the increased activity at the waste ash silo, costs have been included to enclose the three (3) open sides of the silo skirt.

Reverse Air Fabric Filter (RAFF):

- The existing Wheelabrator baghouse has 38 compartments, but at any given time, the baghouse normally has 36 compartments operating with 2 compartments offline for cleaning. The existing cleaning system can clean all 38 compartments in 30 minutes (i.e. can complete two cleaning cycles per hour).
- The existing Wheelabrator baghouse was designed for 1,582,000 ACFM at 185°F. Each compartment has 204 bags (12 rows of 17), for a total of 7,752 bags. The total cloth area of 709,308 ft² results in an air to cloth (A/C) ratio of 2.33:1 when normally operating 36 compartments.
- The new outlet conditions from the 2 SDA modules are estimated to be approximately 2,011,000 ACFM at 174°F. B&W confirmed that the new resulting A/C ratio (approximate 2.8:1) is within their recommended RAFF guidelines and continued operation should not require modifications. However, since the proposed outlet temperature of the 2 SDA modules will be closer to the water saturation temperature, it will be important to prevent moisture from condensing in the baghouse that may potentially cause corrosion.

- The solids loading to the baghouse will be increasing by approximately 70%. Assuming the current pressure drop across the baghouse will be maintained in the new configuration by increased the frequency of cleaning cycles will cause an increased wear on the bags, shortening the bag life to approximately 3-4 years from the current 6 years.

ID Fans:

- The two (2) variable pitch, axial flow induced draft (ID) fans are each rated for 1,279,000 ACFM, 46.71 in. w.c. and 210°F. The incremental increase in pressure for the new configuration is within the capacity of the existing fans. As the fans and motors are in good condition, no modifications are required.

Based on this additional evaluation by Sargent & Lundy and B&W, re-directing Coyote Station's Unit 1 flue gas to two new absorber modules adjacent to the existing fabric filter is considered a technically feasible option.

Revised SO₂ Cost Effectiveness Summary

Budgetary costs estimates were prepared by B&W and reviewed by Sargent & Lundy for the design, procurement, supply, and installation of the new SDA modules and associated balance of plant equipment.

The Four-Factor Analysis cost effectiveness table has been updated to include the associated costs and cost effectiveness for the replacement of the existing DFGD with two new SDA modules and is provided in Table 1 below. Note that since this new option is similar in annualized costs and achieves greater emissions reductions as compared to the prior Four-Factor Analysis option for an in-place absorber, the prior option was removed from the cost effectiveness table. Similarly, since the new two SDA module option is substantially lower in annualized costs and achieves the same emissions reductions as compared to the prior Four-Factor Analysis option for a new Dry FGD, the new Dry FGD option was removed from the cost effectiveness table.

Detailed cost effectiveness tables are included in Appendix A of this memorandum.

Table 1. SO₂ Emissions Control System Cost Effectiveness (\$2018)

SO ₂ Control Option	Total Annualized Cost ^(Note 1) \$/yr	Expected Emission Reduction tons SO ₂ /yr	Average Annual Cost Effectiveness ^(Note 2) \$/ton SO ₂ removed	Incremental Annual Cost Effectiveness ^(Note 3) \$/ton SO ₂ removed
Baseline (existing DFGD/FF)	---	---	---	---
DSI + Existing FGD	\$12,371,000	4,131	\$2,994	
FGD Operational Improvements - Increase Ca:S Stoichiometric Ratio	\$2,082,000	5,354	\$389	
DSI + FGD Operational Improvements	\$14,453,000	7,952	\$1,818	\$4,762
FGD Upgrades - Replace Existing Absorbers with New Absorber (In-Place)	(Removed from Four Factor Analysis)			
FGD Upgrades – Replace Existing Absorbers with Two (2) New Absorbers (Adjacent to Existing FF + Increased Lime Injection)	\$21,122,000	11,619	\$1,818	\$1,819
Dry FGD (CDS) + FF	(Removed from Four Factor Analysis)			
Wet FGD	\$49,035,000	12,078	\$4,060	\$60,813

Note 1. Total annualized costs for all options presented reflect more recent Coyote Station water consumption pricing.

Note 2. Average cost effectiveness for each control option is the total annual cost divided by the expected emission reduction.

Note 3. Incremental cost effectiveness represents the incremental increase in annual costs (\$/yr) divided by the incremental increase in annual emissions reductions (tpy) between a control option and the next most effective option.

Re: Four Factors Analysis - Coyote Station

Dear Mr. Thoma:

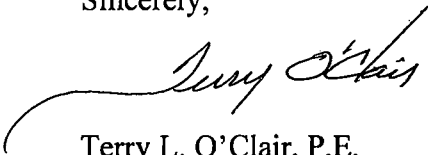

We have reviewed the Four-Factors Analysis for the Coyote Station and have only a few significant comments.

- 1) The baseline emission rates should represent a realistic depiction of anticipated (future) annual emissions for a source (BART Guideline, 4. Step 4). Table 2-1 indicates an expected sulfur content of the lignite combusted in the range of 0.82 – 1.06%. Footnote 1 to Table 5-4 indicates that the inlet SO₂ rate of 3.12 lb/MMBtu to the various scrubbing options is based on a future sulfur content. Normally, a look back at past emissions would be acceptable for determining the baseline emissions. However, since you are anticipating a higher sulfur content in the future lignite combusted, past emissions do not represent a realistic estimate of anticipated emissions. We believe the baseline SO₂ emission rate (12,994 tons/yr) is underestimated in the analysis. The North Dakota Department of Health (Department) has calculated the average SO₂ removal efficiency of the current FGD system from 2013, 2014, 2016, 2017 and 2018 using the AP-42 emission factor of 30(S). Using this average FGD removal efficiency (49%), an average sulfur content of 0.94% (average of 0.82% and 1.06%), and the average coal consumption for the same period (2,204,420 tons/yr), we calculate a baseline emission rate of 15,852 tons/yr. This rate compares very favorably to the 2018 actual emissions (14,913 tons) when adjusting the 2018 sulfur content of 0.89% to 0.94%. The Annual Emissions Inventory Reports for 2016, 2017 and 2018 indicate an increasing sulfur content. The SO₂ analysis should be edited using a more appropriate baseline emission rate.
- 2) We also believe the inlet SO₂ rate to possible control options (3.12 lb/MMBtu) is high. Using the AP-42 emission factor, we calculate an inlet emission rate of approximately 2.3 lb/MMBtu for 1.06% sulfur in the lignite. We believe this will affect the Total Annual Cost and cost effectiveness of the various control options. The analysis should be changed based on a more realistic inlet SO₂ rate.

- 3) The Department included tail-end selective catalytic reduction (SCR) as a technically feasible option in the first Regional Haze planning period. However, as you noted in your analysis, the Department ultimately determined that high dust, low dust and tail-end SCR are not technically feasible for cyclone boilers combusting North Dakota lignite (see *United States of America and the State of North Dakota versus Minnkota Power Cooperative and Square Butte Power Cooperative*). Table 5-10 lists tail-end SCR as a technically infeasible option. Since tail-end SCR is not a technically feasible option, we suggest that it be removed from Tables 5-11, 6-3 and 6-4.
- 4) Many cost estimates throughout the analysis are based on Sargent & Lundy's (S&L) conceptual cost estimating system with major equipment costs based on recently developed projects. When cost estimates are not based on EPA's Control Cost Manual, more documentation is required to substantiate the costs. Please provide the documentation to support costs that are not based on the Control Cost Manual.

If you have any questions, please feel free to contact Tom Bachman of my staff at (701) 328-5188.

Sincerely,

Terry L. O'Clair, P.E.
Director
Division of Air Quality

Re: Regional Haze
Second Planning Period

Dear Mr. Paul:

The Department of Health (Department) has begun work on the second planning period (Round 2) State Implementation Plan (SIP) for regional haze. In Round 1 of the regional planning process, the emphasis was on Best Available Retrofit Technology (BART) and making reasonable progress towards the national visibility goal. In Round 2, there are no BART requirements; therefore, we will focus on making reasonable progress. The reasonable progress analysis will be made using the four factors in Section 169A(g)(1) of the Clean Air Act:

The four factors are:

1. The cost of compliance
2. The time necessary to achieve compliance
3. The energy and non-air quality environmental impact of compliance; and
4. The remaining useful life of any existing source subject to such requirements

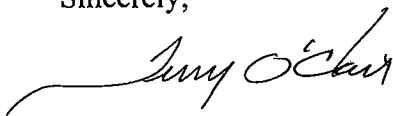

Guidance provided by the U.S. Environmental Protection Agency (Draft Guidance on Progress Tracking Metrics, Long Term Strategies, Reasonable Progress Goals and Other Requirements for Regional Haze State Implementation Plans for the Second Implementation Period at https://www.epa.gov/sites/production/files/2016-07/documents/draft_regional_haze_guidance_july_2016.pdf) indicates the Department must address 80% of the visibility impairment caused by in-state sources. Data from the IMPROVE monitoring sites at Theodore Roosevelt National Park (TRNP) and Lostwood Wilderness Area (LWA) indicate that sulfates and nitrates continue to be the largest contributors to visibility impairment in these areas. The primary precursors of sulfates and nitrates are emissions of sulfur dioxide (SO₂) and nitrogen oxides (NO_x).

Coal-fired electrical generating units have been identified as one of the largest source of sulfur dioxide and nitrogen oxides in North Dakota. Therefore, the Department requests that you prepare a "four factors" analysis for your coal-fired electrical generating units. The analysis should be prepared using the draft EPA guidance noted above. The Department will identify other sources in North Dakota that will be required to submit a four factors analysis.

The Department will be working with the Western Regional Air Partnership (WRAP) to prepare the Round 2 SIP. WRAP will be conducting air quality modeling of regional emissions reductions in early 2019. The Department asks that your "four factors" analysis be submitted by January 31, 2019.

If you have any questions, please contact David Stroh of my staff at (701)328-5188.

Sincerely,

Terry L. O'Clair
Director
Division of Air Quality

Dear Mr. O'Clair:

RE: Four Factor Analysis Submittal for Antelope Valley Station and Leland Olds Station

Enclosed, you will find one CD and three hard copies of Basin Electric Power Cooperative's (**Basin Electric**) Round II Regional Haze Determination Four Factor Analysis for the Antelope Valley and Leland Olds Stations. This analysis was performed as outlined in the North Dakota Department of Health's (**NDDH**) May 2, 2018, request. Basin Electric is aware that the four factor analysis is one component contributing to the NDDH's Round II Regional Haze State Implementation Plan's Determination for each of these emission sources.

North Dakota is relying on the Western Regional Air Partnership (**WRAP**) to develop the visibility modeling platform needed to evaluate visibility at the Class I areas and subsequently for the individual states to develop and assess compliance strategies that will be formalized within the Round II Regional Haze State Implementation Plan.

Basin Electric requests that the NDDH withhold its Round II Regional Haze Determination until a comparative evaluation of visibility from the various control alternatives have been performed. The timing of the visibility analysis is subject to model availability. Basin Electric will continue to monitor WRAP's model development and will coordinate closely with the NDDH prior to initiating visibility impact analysis.

Should you have any questions concerning this submittal, please do not hesitate to contact Erin Dukart, Environmental Compliance Administrator at edukart@bepc.com or 701.557.5557.

Sincerely,

Mike Paul

EXECUTIVE SUMMARY

The Antelope Valley Station (AVS), located near Beulah, North Dakota, has two generating units (Units 1 and 2) each rated at 470 megawatts gross (MWg). AVS Unit 1 went on line in 1984 and Unit 2 went on line in 1986. AVS Units 1 and 2 are Combustion Engineering (CE) pulverized coal (PC), tangential fired units firing North Dakota lignite. Each unit is equipped with an over-fire air (OFA) system, low-NO_x concentric firing system (LNCFS), and Omnivise Combustion Optimizer for NO_x control, a dry lime flue gas desulfurization (DFGD) system, and fabric filter baghouse (FF) control system for SO₂ and particulate matter (PM) control. AVS receives a majority of its lignite fuel from the fine coal rejected by the adjacent Great Plains Syngas Plant (GPSP) coal screening process, with the balance of fuel requirements being delivered directly to AVS from the Freedom Mine, which is located adjacent to the AVS/GPSP Complex.

On July 1, 1999, the U.S. EPA published regulations implementing Section 169A of the Clean Air Act (CAA), establishing a comprehensive visibility protection program for Federal Class I areas (the Regional Haze Rule).¹ The Regional Haze Rule requires each state to develop, and submit for approval by EPA, a state implementation plan (SIP) detailing the state's plan to protect visibility in Class I areas. The Regional Haze Rule established a schedule setting forth deadlines by which the states must submit their initial regional haze SIPs and subsequent revisions to the SIPs. Regional Haze SIPs for the initial planning period were due in 2007, with subsequent SIP updates due in 2018 and every 10 years thereafter.²

During the initial planning period, North Dakota Department of Health's (NDDH) reasonable progress determination found that no NO_x or SO₂ controls were warranted for Basin Electric Power Cooperative's (Basin Electric) AVS Units 1 & 2. U.S. EPA disapproved NDDH's determination for AVS Units 1 & 2, and promulgated a Federal Implementation Plan (FIP) that included a reasonable progress determination that low NO_x burners and separated overfire air (LNB+SOFA) and a NO_x emission limit of 0.17 lb/MMBtu (30-day rolling average) was required for NO_x control for AVS Units 1 and 2. The FIP required Basin Electric to install the NO_x control technologies on AVS Units 1 & 2 by July 31, 2018. In accordance with the FIP requirements, Basin Electric

¹ 64 FR 35713

² On January 10, 2017, EPA made a one-time adjustment to the due date for the second implementation period (2018 – 2028) by extending the deadline from July 31, 2018 to July 31, 2021 (82 FR 3078).

installed a low-NO_x concentric firing system (LNCFS) on AVS Units 1 and 2 in 2014 and 2016, respectively, coinciding with the scheduled tri-annual maintenance outages.

As part of the Round II Regional Haze State Implementation Plan (Round II Determination), NDDH requested that Basin Electric prepare a four-factor analysis of sulfur dioxide (SO₂) and nitrogen oxide (NO_x) emissions control options for AVS Units 1 and 2. The analysis evaluates technically feasible SO₂ and NO_x emission reduction measures for the following four statutory factors:

- Factor 1: The cost of compliance
- Factor 2: The time necessary to achieve compliance
- Factor 3: The energy and non-air quality environmental impact of compliance
- Factor 4: The remaining useful life of any existing source subject to such requirements

Sargent & Lundy LLC (S&L) and Basin Electric evaluated potentially available SO₂ and NO_x emissions reduction options for AVS Units 1 and 2 to identify technically feasible control options for inclusion in the four factor analysis. The SO₂ and NO_x control options included in this four factor analysis are identified in Table ES-1 and Table ES-2.

Table ES-1. Technically Feasible SO₂ Control Options for AVS Units 1 and 2

Alt. No.	SO ₂ Control Technology
E	New Retrofit WFGD
D	New Retrofit DFGD (CDS/FF)
C	New Retrofit DFGD (SDA/FF)
B	FGD Operational Improvements – Increase Ca:S Stoichiometric Ratio
A	FGD Operational Improvements – Station Work Practice
--	Baseline (existing DFGD/FF)

Table ES-2. Technically Feasible NO_x Control Options for AVS Units 1 and 2

Alt. No.	NO _x Control Technology
B	SCR – tail-end configuration ^(Note 1)
A	SNCR
--	Baseline (existing OFA/LNCFS)

Note 1. Tail-end SCR has not been installed on a North Dakota lignite-fired unit, and extended trials would be needed to better understand the design and operation of tail-end SCR on AVS Unit 1. Nevertheless, during the initial planning period, NDDH concluded that tail-end SCR was a technically feasible NO_x control technology for a North Dakota lignite-fired boiler, and evaluated the costs and cost-effectiveness of the control system. For consistency with NDDH's conclusion from the first planning period, tail-end SCR will be carried forward to the four factor analysis

The cost of compliance evaluation (Statutory Factor 1) prepared for SO₂ controls indicates that, from baseline emission rates, the average annual cost effectiveness of the technically feasible SO₂ control options for Unit 1 ranges from \$340 per ton (Alternative A) to \$6,992 per ton SO₂ removed (Alternative E), and for Unit 2 ranges from \$284 per ton (Alternative A) to \$6,861 per ton SO₂ removed (Alternative E). When evaluating projected future maximum emissions reductions, the average annual cost effectiveness of the technically feasible SO₂ control options for Unit 1 ranges from \$623 per ton (Alternative A) to \$6,677 per ton SO₂ removed (Alternative D), and for Unit 2 ranges from \$526 per ton (Alternative A) to \$6,584 per ton SO₂ removed (Alternative D).

The cost of compliance evaluation prepared for NO_x controls indicates that, from baseline emission rates, the average annual cost effectiveness of the technically feasible NO_x control options for Unit 1 ranges from \$19,893 per ton (Alternative A) to \$39,035 per ton NO_x removed (Alternative B), and for Unit 2 ranges from \$18,179 per ton (Alternative A) to \$36,792 per ton NO_x removed (Alternative B). When evaluating projected future maximum emissions reductions, the average annual cost effectiveness of the technically feasible NO_x control options for Unit 1 ranges from \$16,667 per ton (Alternative A) to \$31,977 per ton NO_x removed (Alternative B), and for Unit 2 ranges from \$15,910 per ton (Alternative A) to \$31,589 per ton NO_x removed (Alternative B).

The time necessary for compliance (Statutory Factor 2) for the SO₂ control options ranges from 3 months (Alternative A) to 60 months (Alternative E). For NO_x control options, the time necessary for compliance ranges from 22 months (Alternative A) to 52 months (Alternative B).

An evaluation of energy impacts and non-air environmental impacts (Statutory Factor 3) indicates that certain control options will increase auxiliary power requirements due to increased pressure drop, which would adversely impact net plant heat rate. Consequently, heat input to the boiler would need to increase to compensate for the

increased auxiliary power requirements while achieving the same net plant output, or net output from the unit would decrease. Collateral environmental impacts include increases in water consumption, FGD wastewater treatment and discharge, solid waste generation, and sulfuric acid mist and ammonia emissions.

Regarding remaining useful life (Statutory Factor 4), under the current Basin Electric resource plan, the remaining useful life of AVS Units 1 and 2 are considered to be greater than 20 years. Therefore, the remaining useful life has no impact on the annualized cost of control under the current regulatory framework.

Based on the results of the four factor analysis prepared for AVS, Basin Electric is aware that reducing SO₂ emissions by implementing FGD Operational Improvements (Alternative B) on Units 1 and 2 may be determined to be cost effective by the NDDH.

Within the Round II Determination process, the NDDH will evaluate visibility improvements relying on Western Region Area Partnership's (WRAP) cumulative modeling of the North Dakota based facilities for the various control options being evaluated. Basin Electric requests that the NDDH withhold their Round II Regional Haze SIP Determination for the AVS until the cumulative modeling platform is made available to the public and visibility improvement assessments can be conducted. Basin Electric will then perform a comparative visibility improvement analysis and submit the results to the NDDH for consideration. This effort will be coordinated with the NDDH for consistency of modeling protocols and model inputs.

In addition, Basin Electric requests, that in the event that SO₂ reductions will be required, any future 30-day rolling average permit limit will be based on an equivalent mass based combined plant (lb SO₂/hr) 30-day rolling average basis. Since AVS began operation, the current combined plant total permit limit of 3,845 lb SO₂/hr, 3-hour average, has been the benchmark for all operations guidance and procedures and is imbedded in the DFGD process control logic. To alter the basis of the operational control to a mass emission rate (lb SO₂/MMBtu) will be extremely disruptive from an operational perspective when consideration is given to the complexity and variability of DFGD operations.

The four factor analysis prepared for AVS NO_x reductions indicates that SNCR and tail-end SCR control options are cost prohibitive. The control cost evaluation indicates that the average cost effectiveness levels exceed \$15,000 per ton NO_x removed. Basin Electric is proposing that the existing OFA / LNCFS systems on Units 1 and 2 represent appropriate controls for the Round II Determination, therefore no change to the current Title V Operating Permit is proposed for NO_x emissions at AVS. Table ES-3 includes a summary of the proposed Round II

Determination's control strategy for SO₂, assessed SO₂ emissions on a 30-day rolling average basis and a proposed combined plant average emission rate for AVS. The proposed emissions include compliance margin to account for items such as variability in fuel heating value and sulfur content, and operating load profile.

Table ES-3. Proposed Round II Determination's SO₂ Emission Rate

AVS Unit No.	Pollutant	Proposed Round II Determination's Emission Rate lb/MMBtu (30-day rolling average)	Proposed Round II Determination's Combined Plant Emission Rate (Note 1) (lb/hr)	Control Technology
Unit 1	SO ₂	0.30	2,958	FGD Operational Improvements
Unit 2	SO ₂	0.30	2,958	FGD Operational Improvements

Note 1. The proposed Round II Determination's combined plant emission rate is a 23% reduction from the current combined plant permit limit of 3,845 lb SO₂/hr, 3-hour avg.

1. INTRODUCTION

Sargent & Lundy, L.L.C. (S&L) was retained by Basin Electric Power Cooperative (Basin Electric) to prepare a Round II Regional Haze State Implementation Plan Determination's (Round II Determination) four-factor analysis for the control of sulfur dioxide (SO₂) and nitrogen oxide (NO_x) emissions from Basin Electric's Antelope Valley Station (AVS) Units 1 and 2. The evaluation is in response to the North Dakota Department of Health's formal letter dated May 2, 2018, attached in Appendix A. The evaluation includes an assessment of potentially available emission reduction measures for the four statutory factors listed in 40 CFR 51.308(f)(2), and takes into consideration U.S. Environmental Protection Agency's (EPA's) *Draft Guidance on Progress Tracking Metrics, Long Term Strategies, Reasonable Progress Goals and Other Requirements for Regional Haze State Implementation Plans for the Second Implementation Period* (the "Draft EPA Guidance").³ Technically feasible SO₂ and NO_x emission reduction measures are evaluated for the following four statutory factors:

- Factor 1: The cost of compliance
- Factor 2: The time necessary to achieve compliance
- Factor 3: The energy and non-air quality environmental impact of compliance
- Factor 4: The remaining useful life of any existing source subject to such requirements

The Round II Determination's four factor analysis for AVS Units 1 and 2 is presented in the following sections:

- Section 2: Facility Description** contains information describing the facility, site location, and existing equipment.
- Section 3: Four-Factor Analysis Requirements** provides a brief description of the Regional Haze Program requirements set forth in 40 CFR 51.308.
- Section 4: SO₂ Control Evaluation** establishes representative baseline SO₂ emissions, identifies potentially available emission control technologies, evaluates each control option for technical feasibility and evaluates cost effectiveness of technically feasible control options.
- Section 5: NO_x Control Evaluation** establishes representative baseline NO_x emissions, identifies potentially available emission control technologies, evaluates each control option for

³ On September 11, 2018, EPA released a "*Regional Haze Reform Roadmap*" announcing its plan to "release a series of implementation tools and guidance documents that will help focus states' efforts and reduce and streamline the time and resources needed to meet the statutory and regulatory requirements for reducing regional haze in National Parks, wildlife refuges, and wilderness areas." EPA stated that it plans to issue a new guidance document on Regional Haze SIP Development by Spring, 2019. Basin Electric reserves the right to update and modify this four-factor analysis, as needed, to be consistent with any new guidance issued by the agency.

technical feasibility and evaluates cost effectiveness of technically feasible control options.

Section 6: Time Necessary for Compliance provides typical timelines required to design, engineer, procure and install the technically feasible control options.

Section 7: Energy and Non-Air Quality Environmental Impacts identifies the energy and non-air quality environmental impacts associated with each technically feasible control option.

Section 8: Remaining Useful Life includes a discussion of the planned remaining useful life of AVS Units 1 and 2, including an evaluation of how remaining useful life affects the cost-effectiveness of each technically feasible control option.

Section 9: Summary and Conclusions

Appendix A: North Dakota Department of Health Letter

Appendix B: Antelope Valley Station Units 1 and 2 Baseline Emissions

Appendix C: SO₂ Control Cost Effectiveness Estimates

Appendix D: NO_x Control Cost Effectiveness Estimates

2. FACILITY DESCRIPTION

The Antelope Valley Station (AVS), located near Beulah, North Dakota, has two generating units (Units 1 and 2) each rated at 470 megawatts gross (MWg). AVS Unit 1 went on line in 1984 and Unit 2 went on line in 1986. AVS Units 1 and 2 are Combustion Engineering (CE) pulverized coal (PC), tangential fired units firing North Dakota lignite. Each unit is equipped with an over-fire air (OFA), low-NO_x concentric firing system (LNCFS), and Omnivise Combustion Optimizer for NO_x control, a dry lime flue gas desulfurization (DFGD) system, and fabric filter baghouse (FF) control system for SO₂ and PM control. AVS receives a majority of its lignite fuel from the fine coal rejected by the adjacent Great Plains Syngas Plant (GPSP) coal screening process, with the balance of fuel requirements being delivered directly to AVS from the Freedom Mine, which is located adjacent to the AVS/GPSP Complex.

Table 2-1 provides a summary of the design parameters used for the AVS Units 1 and 2 four factor analysis. The four factor analysis design parameters listed in Table 2-1 were developed from information provided by Basin Electric. The parameters are for each AVS unit.

Table 2-1. Four Factor Analysis Design Basis Parameters

Parameter	AVS Unit 1	AVS Unit 2
Boiler type	PC tangential fired	PC tangential fired
Boiler manufacturer	Combustion Engineering	Combustion Engineering
Generating Capacity (MWg)	470	470
Design Heat Input (MBtu/hr)	4,930	4,930
Average Hourly Heat Input for Baseline SO ₂ period (MBtu/hr)	4,459	4,499
Capacity Factor for Baseline SO ₂ period (%)	86	87
Average Hourly Heat Input for Baseline NO _x period (MBtu/hr)	4,126	4,480
Capacity Factor for Baseline NO _x period (%)	81	85

NORTH DAKOTA ROUND II REGIONAL HAZE SIP
 DETERMINATION'S FOUR-FACTOR ANALYSIS FOR ANTELOPE
 VALLEY STATION UNITS 1 AND 2

2-2

Parameter	AVS Unit 1	AVS Unit 2
DFGD Design Parameters		
SO ₂ Content lb/MMBtu	3.56	3.56
Design Removal Efficiency (%)	89	89
Baseline Fuel Parameters ⁽¹⁾		
Higher Heating Value (Btu/lb)	6,755	6,755
Fuel sulfur content (%)	0.98	0.98
SO ₂ content (lb/MMBtu)	2.90	2.90
Projected Future Fuel Parameters ⁽²⁾		
Higher Heating Value (Btu/lb)	6,434	6,434
Fuel sulfur content (%)	1.09	1.09
SO ₂ content (lb/MMBtu)	3.39	3.39

Note 1. Baseline fuel parameters are based on the actual annual average fuel sulfur content from 2013-2018 provided by Basin Electric.

Note 2. Projected future fuel parameters are based on anticipated annual average coal projections provided by Basin Electric from 2019-2045. Projected future sulfur and SO₂ content includes margin based on the actual deviation in annual average sulfur content from current coal data. Additional detail on coal sulfur provided in Section 4.2.

3. FOUR-FACTOR ANALYSIS REQUIREMENTS

3.1 REGIONAL HAZE RULE BACKGROUND

Section 169A of the 1977 Amendments to the Clean Air Act (CAA) sets forth a program for protecting visibility in Federal Class I areas which calls for “the prevention of any future, and the remedying of any existing, impairment of visibility in mandatory Federal Class I areas which impairment results from manmade air pollution.” Federal Class I areas include national parks, memorial parks, and wilderness areas over a certain size. Figure 3-1 shows the locations of the 156 federally mandated Class I areas. Federal Class I areas located within ND include the Theodore Roosevelt National Park and the Lostwood National Wildlife Refuge.

Figure 3-1. Federal Class I Areas

On July 1, 1999, the U.S. EPA published regulations implementing Section 169A of the CAA, establishing a comprehensive visibility protection program for Federal Class I areas (the Regional Haze Rule).⁴ The Regional Haze Rule requires each state to develop, and submit for approval by EPA, a state implementation plan (SIP) detailing the state's plan to protect visibility in Class I areas. Regional Haze SIPs must contain such emission limits, schedules of compliance, and other measures as may be necessary to make reasonable progress toward meeting the national visibility goal of achieving visibility in Class 1 areas which reflects natural conditions by 2064.

To address the combined visibility effects of various pollution sources over a wide geographic region, EPA designated five Regional Planning Organizations (RPOs) to assist with the coordination and cooperation needed to address the visibility issue. The five RPOs are shown in Figure 3-2. North Dakota is a member of the Western Regional Air Partnership (WRAP), which serves as the RPO for visibility protection at 118 Class I areas in 15 western states.

Figure 3-2. Regional Planning Organization Map

⁴ 64 FR 35713

3.1.1 First Implementation Period

The Regional Haze Rule established a schedule setting forth deadlines by which the states must submit their initial regional haze SIPs and subsequent revisions to the SIPs. Regional Haze SIPs for the initial planning period were due in 2007, with subsequent SIP updates due in 2018 and every 10 years thereafter.⁵

Regional Haze SIP requirements for the first planning period required that states incorporate into their plans the core program requirements in 40 CFR 51.308(d), including: (1) establishing reasonable progress goals (RPGs) for each Class I area within the state that provide for measurable progress towards achieving natural visibility conditions; (2) developing a long-term strategy (LTS) including enforceable emissions limitations and compliance schedules to achieve the RPGs; and (3) developing plans to monitor and assess the effectiveness of the LTS to achieve the RPGs over the prior implementation period and affirmation of or revision to the RPGs.

The Regional Haze Rule requires that states determine the consistent rate of progress over time needed to attain natural visibility conditions on the 20 percent most impaired days by the year 2064. This “glidepath” is referred to as the uniform rate of progress (URP) line. States must consider the URP, and the emission reduction measures needed to achieve this level of improvement, when developing their RPGs and LTS. Regulations at 40 CFR 51.308(g) require each state to submit progress reports, in the form of SIP revisions, every 5 years following the submission of the initial SIP. These progress reports must evaluate the progress made towards the RPGs for Class I areas located within the state as well as those Class I areas located outside the state that may be affected by emissions from within the state.

3.1.1.1 Best Available Retrofit Technology

As a one-time requirement during the first implementation period, potential best available retrofit technology (BART) controls had to be evaluated for certain large stationary sources. States were required to conduct BART determinations for “BART-eligible” sources anticipated to cause or contribute to any visibility impairment in one or more Class I area. BART-eligible sources included coal-fired electric generating units (EGUs) that were in existence on August 7, 1977, but not in operation prior to August 7, 1962. In its determination of BART, states were required to take into consideration the costs of compliance, the energy and non-air quality environmental impacts of compliance, any existing pollution control technology in use at the source, the remaining useful life of

⁵ On January 10, 2017, EPA made a one-time adjustment to the due date for the second implementation period (2018 – 2028) by extending the deadline from July 31, 2018 to July 31, 2021 (82 FR 3078).

the source, and the degree of improvement in visibility which may reasonably be anticipated to result from the use of such technology.⁶ As an alternative to requiring source-specific BART controls, states also had the flexibility to adopt an emissions trading program or other alternative program as long as the alternative provided greater reasonable progress towards improving visibility than BART.

3.1.1.2 North Dakota's Initial Planning Period SIP Summary

The State of North Dakota submitted its regional haze SIP addressing the requirements of 40 CFR 51.308 to EPA for review on March 3, 2010 (the "Regional Haze SIP").⁷ The Regional Haze SIP was prepared by the North Dakota Department of Health, Air Quality Division (NDDH). The SIP included BART determinations for seven steam EGU's identified as being subject to the BART requirements of 40 CFR 51.208(e) and a reasonable progress evaluation for six additional non-BART sources identified as having the potential to affect visibility in a Class I area.

Basin Electric's Leland Olds Station (LOS) Units 1 & 2 were evaluated by NDDH as subject-to-BART sources.⁸ Based on its evaluation of available control technologies, NDDH concluded that BART for both LOS units included new wet flue gas desulfurization (WFGD) for SO₂ control and separated overfire air (SOFA) with selective non-catalytic reduction (SNCR) for NO_x control. NDDH determined that selective catalytic reduction (SCR), a higher performing NO_x control option, was not an available, and thus not a technically feasible, NO_x control option.⁹

Basin Electric's AVS Units 1 & 2 were evaluated by NDDH under the further reasonable progress requirements. Based on an evaluation of the four reasonable progress statutory factors (i.e., costs of compliance, time necessary

⁶ CAA Section 169A(g)(2).

⁷ North Dakota State Implementation Plan for Regional Haze – A Plan for Implementing the Regional Haze Program Requirements of Section 308 of 40 CFR Part 51, Subpart P – Protection of Visibility, North Dakota Department of Health, February 24, 2010. In addition to the initial SIP submittal, the State submitted a SIP Supplement No. 1 on July 27, 2010, and a SIP Amendment No. 1 on July 28, 2011 (collectively the "Regional Haze SIP").

⁸ In addition to LOS Units 1 & 2, NDDH evaluated Great River Energy's Coal Creek Station Units 1 & 2; Great River Energy's Stanton Station Unit 1; and Minnkota Power Cooperative's Milton R. Young Station Units 1 & 2 as subject-to-BART sources.

⁹ Regional Haze SIP, pg. 73. The State's evaluation of SCR for North Dakota lignite was included as Appendix B.5 to the Regional Haze SIP (Best Available Retrofit Technology – Selective Catalytic Reduction Technical Feasibility Analysis for North Dakota Lignite, July 2009). NDDH eliminated SCR from consideration as BART based on a finding that SCR was not technically feasible to control emissions from North Dakota lignite coal. In particular, NDDH noted that no SCR has ever been employed on an electric generating unit (EGU) burning North Dakota lignite, that North Dakota lignite has unique properties that have the potential to quickly degrade the SCR catalyst, and that no catalyst vendor would provide a guarantee of catalyst life without first conducting slipstream or pilot testing.

for compliance, energy and non-air quality environmental impacts of compliance, and the remaining useful life of the units) plus an evaluation of incremental visibility improvement, NDDH concluded that requiring additional controls (beyond those required for the BART-eligible sources) would not substantially improve visibility in the Class I areas, and that for all reasonable progress sources evaluated individually and cumulatively, control technology costs (evaluated on a dollar per deciview improvement (\$/dv) basis) was excessive. Therefore, the initial Regional Haze SIP did not include additional control for AVS Units 1 & 2.¹⁰

On September 21, 2011, EPA published a Proposed Rule proposing to partially approve and partially disapprove specific aspects the Regional Haze SIP.¹¹ Among other things, EPA proposed to disapprove the State's determination of BART for LOS Unit 2 as well as the reasonable progress determination for AVS Units 1 & 2. EPA proposed to approve the remaining aspects of North Dakota's Regional Haze SIP, including that State's BART determination for SO₂ control at LOS (i.e., new WFGD) and the NO_x BART determination for LOS Unit 1 (i.e., SOFA+SNCR).¹² Along with the proposed partial disapproval of North Dakota's SIP, EPA proposed the promulgation of a Federal Implementation Plan (FIP). The proposed FIP included, among other items: (1) a NO_x BART determination and emission limits for LOS Unit 2; and (2) a reasonable progress determination and NO_x emission limits for AVS Units 1 & 2. EPA proposed advanced SOFA (ASOFA) plus SCR and an emission rate of 0.07 lb/MMBtu (30-day rolling average) as BART for NO_x control on LOS Unit 2. EPA also proposed low-NO_x burners (LNB) plus SOFA and an emission limit of 0.17 lb/MMBtu (30-day rolling average) as representing reasonable progress NO_x control on AVS Units 1 & 2.¹³

¹⁰ *Id.* at pg. 188.

¹¹ 76 Fed. Reg. 58570, September 21, 2011 (the "Proposed FIP"). In addition to the proposed disapproval of the State's BART determination for Leland Olds Station Unit 2, EPA proposed disapproving the BART determinations for the Coal Creek Station and Milton R. Young Station (MRYS) Units 1 & 2.

¹² *Id.* at pg. 58619. Note that for LOS Unit 1 EPA stated that it did not agree with the State's cost analysis for SCR, but nonetheless found the elimination of SCR for LOS Unit 1 to be acceptable because LOS Unit 1 is relatively small (216 MW) compared to LOS Unit 2 (440 MW) and MRYS Units 1 & 2, and LOS Unit 1 had lower baseline NO_x emission. (76 FR 58596, Table 22).

¹³ *Id.* at pg. 58632. EPA eliminated higher performing NO_x control options for AVS Units 1 & 2, including LNB + SNCR; SCR; and LNB + SCR, because their cost effectiveness values were significantly higher and/or the emission reductions were not that much higher than LNB. Considering the statutory factors, EPA found that it was not reasonable to insist on these higher control levels in the first; however, EPA noted that expected North Dakota to consider such controls in the next planning period.

Following the public notice and comment period EPA issued its Final Rule on April 6, 2012.¹⁴ The Final Rule differed from the Proposed Rule in that EPA reversed its position regarding the technical feasibility of SCR on LOS Unit 2 and decided to approve the State's BART determination for NO_x control on LOS Unit 2.¹⁵ Conversely, EPA finalized its determination that LNB+SOFA was required by reasonable progress for AVS Units 1 & 2.

EPA's decision to accept the BART determinations for LOS Unit 2 (and Milton R. Young Station (MRYS) Units 1 & 2) was based primarily on the decision in United States v. Minnkota Power Cooperative, Inc.¹⁶ which concluded that the State's best available control technology (BACT) analysis for NO_x control on MRYS Units 1 & 2 was not unreasonable, a conclusion that was contrary to EPA's position at the time of the Proposed FIP.¹⁷ In explaining its decision to reverse its position that SCR was a technically feasible NO_x control option for LOS Unit 2, EPA noted that the technical feasibility determination under the BACT and BART analyses was substantially the same, and that the BART Guidelines permit a state to rely upon a BACT determination for purposes of selecting BART unless new technologies have become available or best control levels for recent retrofits have become more stringent.¹⁸ Noting that the District Court upheld North Dakota's BACT determination for MRYS Units 1 & 2, EPA concluded that it would be inappropriate to proceed with its proposed disapproval of SNCR as BART, and approved the State's determination that ASOFA+SNCR and an emission rate of 0.35 lb/MMBtu (30-day rolling average) was BART for NO_x control on LOS Unit 2.

With respect to NO_x control on AVS Units 1 & 2, EPA finalized its proposed determination that LNB+SOFA and a NO_x emission rate of 0.17 lb/MMBtu (30-day rolling average) was required for reasonable progress. North Dakota challenged EPA's disapproval of its reasonable progress determination for AVS Units 1 & 2, and EPA's subsequent promulgation of the FIP. The District Court found that EPA's determination on this matter was entitled to judicial

¹⁴ 77 Fed. Reg. 20894.

¹⁵ *Id.* at pg. 20897-98. EPA also reversed its position and decided to approve the State's BART determination for NO_x control on MRYS Units 1 & 2.

¹⁶ United States v. Minnkota Power Cooperative, Inc., 831 F. Supp. 2d 1109, 1127-30 (D.N.D. 2011).

¹⁷ Contemporaneous with the Regional Haze SIP/FIP process, NDDH was also determining BACT for MRYS Units 1 & 2 pursuant to a Consent Decree entered into between the owner of the station (Minnkota), the State, and EPA under the CAA's Prevention of Significant Deterioration program. In its BACT analysis, NDDH concluded that SCR was technically infeasible on a lignite-fired cyclone boiler, and selected SNCR as BACT. EPA challenged the State's BACT determination in district court, contending that SCR was a technically feasible emission control option and should have been selected as BACT. On December 21, 2011, the District Court issued its decision on EPA's challenge of the State's BACT determination, finding that the State's conclusion that SCR was not technically feasible was not unreasonable. See, *U.S. v. Minnkota*, 831 F. Supp. 2d at 1127-30.

¹⁸ 77 Fed. Reg. 20897.

deference, and could not conclude that EPA acted in a manner that was arbitrary or capricious; therefore, the State's petition for review was denied and EPA's reasonable progress determination for AVS Units 1 & 2 was upheld.

Emission controls required by the Regional Haze SIP for the Basin Electric's LOS and AVS stations are summarized in Table 3-1.

Table 3-1. Initial Planning Period SIP Summary

Source & Unit	Pollutant	Control Device / Emission Limit
LOS Unit 1 (BART)	NO _x	Basic SOFA + SNCR with an emission limit of 0.19 lb/MMBtu (30-day rolling average)
	SO ₂	New wet FGD operating at 95% efficiency or below an emission limit of 0.15 lb/MMBtu (30-day rolling average)
LOS Unit 2 (BART)	NO _x	Advanced SOFA + SNCR with an emission limit of 0.35 lb/MMBtu (30-day rolling average)
	SO ₂	New wet FGD operating at 95% efficiency or below an emission limit of 0.15 lb/MMBtu (30-day rolling average)
AVS Unit 1 (reasonable progress)	NO _x	LNB+SOFA with an emission limit of 0.17 lb/MMBtu (30-day rolling average)
	SO ₂	No additional control beyond the existing dry FGD / baghouse
AVS Unit 2 (reasonable progress)	NO _x	LNB+SOFA with an emission limit of 0.17 lb/MMBtu (30-day rolling average)
	SO ₂	No additional control beyond the existing dry FGD / baghouse

3.1.1.3 Reasonable Progress Control Requirements for AVS Units 1 and 2 during First Planning Period

AVS Units 1 & 2 were not subject to the Regional Haze BART requirements of 40 CFR 51.208(e). Nevertheless, during the initial planning period NDDH evaluated emissions reductions from AVS as a reasonable progress source. Based on an evaluation of control technology costs and the resulting incremental improvement in visibility, NDDH found that no additional NO_x controls were warranted during the initial planning period. As discussed in Section 3.1.1.2, EPA disapproved the State's reasonable progress determination for AVS Units 1 & 2, and promulgated a FIP that included a reasonable progress determination that LNB+SOFA and a NO_x emission limit of 0.17 lb/MMBtu (30-day rolling average) was required for NO_x control for AVS Units 1 and 2. The FIP required Basin Electric to install the NO_x control technologies on AVS Units 1 & 2 by July 31, 2018. In accordance with the FIP requirements, Basin Electric installed a low-NO_x concentric firing system (LNCFS) on AVS Units 1 and 2 in 2014 and 2016, respectively, coinciding with the scheduled tri-annual maintenance outages.

3.1.2 Round II Regional Haze SIP Determination

The Round II Determination must be submitted to EPA for review by July 31, 2021. Among other requirements, the Round II Determination is required to include an assessment of the state's RPGs and LTS. To support states in their efforts to develop the Round II Determination, in July 2016 EPA released a draft guidance document titled *"Draft Guidance on Progress Tracking Metrics, Long-term Strategies, Reasonable Progress Goals and Other Requirements for Regional Haze State Implementation Plans for the Second Implementation Period"* ("Draft EPA Guidance").¹⁹ The Draft EPA Guidance document describes key steps states should implement when developing their RPGs and LTS for the Round II Determination. Key steps identified in the Draft EPA Guidance are listed in Table 3-2.

¹⁹ See, EPA-457/P-16-001. On September 11, 2018, EPA released a *"Regional Haze Reform Roadmap"* announcing its plan to "release a series of implementation tools and guidance documents that will help focus states' efforts and reduce and streamline the time and resources needed to meet the statutory and regulatory requirements for reducing regional haze in National Parks, wildlife refuges, and wilderness areas." EPA stated that it plans to issue a new guidance document on Regional Haze SIP Development by Spring, 2019. Basin Electric reserves the right to update and modify this four-factor analysis, as needed, to be consistent with any new guidance issued by the agency.

Table 3-2. Key Steps in Developing the Round II Determination

1. *Ambient data analysis* – Quantify baseline, current and natural conditions and the uniform rate of progress that would achieve natural conditions by 2064 (40 CFR 51.308(f)(1))
2. *Screening of sources* – Identify the pollutants and emission sources for which a full reasonable progress analysis will be completed and explain why it is appropriate to limit the full analysis to only these sources (40 CFR 51.308(f)(2))
3. *Source and emission control measure analysis* – Identify potential emission control measures for sources selected in the screening step and develop data on the four statutory factors and visibility benefits if they will be considered (40 CFR 51.308(f)(2))
4. *Decisions on the content of the LTS* – Consider applicable factors and decide on new emission controls for incorporation into the LTS (40 CFR 51.308(f)(2))
5. *Regional scale modeling* – Model the emissions reductions that will result from implementation of the LTS and other enforceable measures that will reduce visibility impairment to set the RPGs for 2028 (40 CFR 51.308(f)(3))
6. *Progress, degradation and glidepath checks* – Demonstrate that there will be an improvement on the 20 percent most impaired days. Demonstrate that there is no degradation on the 20 percent clearest days. Compare the 2028 RPG for the 20 percent most impaired days to the 2028 point on the URP line (the glidepath) and, if required, provide additional justification for the reasonableness of the RPG. Revise the LTS if additional measures are identified as necessary to make reasonable progress. (40 CFR 51.308(f)(3))
7. *Additional requirements for SIPs* – Provide additional information necessary to ensure that other requirements of the Regional Haze rule are met.

The Draft EPA Guidance recommends that states evaluate all technically feasible emission control options for stationary sources and source categories identified as having the greatest potential to impact visibility at one or more Class I area. The Draft EPA Guidance recommends several options for states to consider when evaluating potential emission reductions, including work practices, replacement and retrofit controls, existing control upgrades, fuel switching, year-round operation of controls, and operating restrictions.²⁰

Emission control evaluations must consider the four statutory factors identified in 40 CFR 51.308(f)(2)(i) (discussed in Section 3.2). In addition, the Draft EPA Guidance notes that control technology assessment recommendations presented in the BART Guidelines continue to be relevant as recommendations for how a state should evaluate and select emission control measures for stationary sources.²¹ Recommendations in the BART

²⁰ See, Draft EPA Guidance, pgs. 85-86.

²¹ Draft EPA Guidance, pg. 85. The BART Guidelines are published at 40 CFR Part 51 Appendix Y.

Guidelines that continue to be relevant to the Round II Determination's four factor analysis are listed in the Appendix of the Draft EPA Guidance, and include, in general, the recommended approach for evaluating the technical feasibility, effectiveness, costs, and cost-effectiveness of available emission control measures.²²

3.2 DESCRIPTIONS OF THE FOUR STATUTORY FACTORS

Under 40 CFR 51.308(f)(2)(i), states must consider four statutory factors when evaluating and determining emissions reduction measures from stationary sources, or groups of sources, that are necessary to make reasonable progress towards achieving natural visibility conditions. The four statutory factors are:

1. The costs of compliance;
2. The time necessary for compliance;
3. The energy and non-air quality environmental impacts of compliance; and
4. The remaining useful life of any potentially affected anthropogenic source of visibility impairment.

A brief description of each of the four statutory factors, and EPA's recommendations for evaluating each of the four factors (from the Draft EPA Guidance) is provided below.

3.2.1 Costs of Compliance

Cost estimates should be developed for each technically feasible control option. Costs include the total capital costs to engineer, design, procure, and install the control technology, and annual operating and maintenance (O&M) costs. O&M costs include both fixed and variable O&M. Fixed O&M includes costs that are independent of control system operation and would be incurred even if the control system were shut down. Fixed O&M includes categories such as operating and maintenance labor, administrative charges, property taxes, and insurance. Variable O&M includes the cost of consumables, including reagent (e.g., lime or limestone, ammonia, urea, etc.), by-product management, water consumption, and auxiliary power requirements associated with operating the control system. For existing facilities, O&M cost estimates should represent the control option's incremental increase over current O&M costs.

Capital costs include all costs required to engineer, design, procure, and install equipment needed for the control system. The Draft EPA Guideline recommends that states adhere to the accounting principles described in Chapter

²² Draft EPA Guidance, Appendix D, pgs. 186-196.

2 Section 1 of EPA's Air Pollution Control Cost Manual (the "Control Cost Manual") when calculating control system costs for a four factor analysis.²³

Section 2.3 of the Control Cost Manual (Section 1, Chapter 2) describes the cost categories generally used to calculate the total capital cost of a retrofit control technology. Cost categories include total capital investment (TCI), which is defined to "include all costs required to purchase equipment needed for the control systems (purchased equipment costs), the costs of labor and materials for installing that equipment (direct installation costs), costs for site preparation and buildings, and certain other costs (indirect installation costs). TCI also includes costs for land, working capital, and off-site facilities." Direct installation costs include costs for foundations and supports, erecting and handling the equipment, electrical work, piping, insulation, and painting. Indirect installation costs include costs such as engineering costs; construction and field expenses (i.e., cost for construction supervisory personnel, office personnel, rental of temporary offices, etc.); contractor fees (for construction and engineering firms involved in the project); start-up and performance test costs (to get the control system running and to verify that it meets performance guarantees); and contingencies.²⁴

The total annual cost (TAC) of a control option includes the annualized capital recovery cost plus the total annual O&M costs. The Control Cost Manual recommends using an equivalent uniform annual cash flow method to annualize the total capital investment by multiplying the total capital investment by a capital recovery factor (CRF).²⁵ The product of the total capital investment and CRF gives a uniform end-of-year payment necessary to repay the initial capital investment in "n" years at an interest rate of "i". The CRF is calculated using the following equation:

$$CRF = \frac{i * (1 + i)^n}{(1 + i)^n - 1}$$

Where:

i = interest rate; and

n = economic life of the emission control system

The Draft EPA Guidance suggests that states may use generic cost estimates or estimating algorithms for estimating control system costs; however, source specific estimates prepared by knowledgeable engineering professionals

²³ EPA Air Pollution Control Cost Manual, Sixth Edition, EPA/452/B-02-001, January 2002.

²⁴ EPA Air Pollution Control Cost Manual, Sixth Edition, EPA/452/B-02-001, January 2002, pg. 2-5.

²⁵ Id., at pg 2-21.

provide more reliable information than generic cost estimates.²⁶ Source-specific cost estimate should be well documented for purposes of public comment and EPA review.²⁷

The total annual cost of each control option (\$/yr) is divided by the total annual emissions reduction (tpy) to determine the control option's average cost-effectiveness on a \$/ton basis. Emissions reductions are calculated based on the difference between baseline annual emissions and post-control annual emissions. The Draft EPA Guidance generally recommends calculating baseline emissions based on projected 2028 emissions assuming source compliance with emission limits that have been adopted and are enforceable. As an alternative, baseline emissions may be based on representative past actual emissions, assuming there is no evident basis for using a different emissions rate.

3.2.2 Time Necessary for Compliance

For stationary sources, the provisions of the BART Guidelines regarding the time necessary for compliance are relevant to the Round II Determination's analyses. EPA recommends that prior experiences with the planning and installation of new emission controls is the best guide to how much time a particular source will reasonably need for compliance. However, source-specific factors should be considered when evaluating the time necessary to engineer, procure, and install an available and technically feasible control option. Source-specific factors that affect the time necessary to install new emission controls should be identified and documented in the four factor analysis.

3.2.3 Energy and Non-Air Quality Environmental Impacts

For stationary sources, the provisions of the BART Guidelines regarding energy impacts are relevant to the Round II Determination's analyses. Energy impacts of an emission control measure are a matter of engineering design and control system operation; thus, EPA recommends that prior experience at similar sources will be informative. Energy impacts may be considered in terms of kilowatt-hours or fuels used to operate the control system. The energy impact analysis should focus on direct energy consumption at the source rather than indirect energy inputs needed to produce raw materials for the construction and operation of control equipment.

²⁶ Draft EPA Guidance, pg. 91.

²⁷ *Id.*

For stationary sources, the provisions of the BART Guidelines regarding non-air quality environmental impacts are relevant to the Round II Determination's analyses. Non-air quality impacts include solid or hazardous waste generation, increased water consumption, wastewater discharge, land use impacts, and impacts to threatened and endangered species or their natural habitat. Characterizing the non-air quality environmental impacts should be done on a source-specific basis. Other guidance intended for use in assessments under the National Environmental Policy Act may be relevant to this evaluation.

Even though states are not required to consider GHG emission impacts, the Draft EPA Guidance encourages states to consider GHG impacts when developing their LTS.²⁸ As an example, some measures that would reduce emissions that contribute to visibility impairment will also reduce GHG emissions, such as measures that reduce the use of energy produced from combusting fossil fuels with relatively high GHG emissions. Conversely, control measures that require significant energy to capture visibility impairing emissions could result in increased GHG emission. Where a measure necessary to make reasonable progress towards natural visibility conditions would increase GHG emissions, Draft EPA Guidance encourages states to work to harmonize visibility and climate change objectives.²⁹

3.2.4 Remaining Useful Life

For stationary sources, the provisions of the BART Guidelines regarding remaining useful life are relevant to the Round II Determination's analyses. In general, the remaining useful life of the source itself will be longer than the useful life of the emission control measure under consideration unless there is an enforceable requirement for the source to cease operation sooner. Thus, the useful life of the control measure will normally be used in the four factor analysis to calculate emission reductions, amortized costs, and cost-effectiveness. However, if there is an enforceable requirement for the source to cease operation by a date before the end of what would otherwise be the useful life of the control measure under consideration, then the enforceable shutdown date should be used to calculate remaining useful life and evaluate control technology cost-effectiveness.

²⁸ Draft EPA Guidance, pg. 92.

²⁹ *Id.*

3.2.5 Approach for Evaluating Control Measures

S&L used a top-down approach to identify and evaluate the technical feasibility and effectiveness of potentially available SO₂ and NO_x control measures. S&L followed Steps 1 thru 3 of the top-down approach described in the BART Guidelines to identify all available retrofit emission control measures, eliminate technically infeasible options, and evaluate the effectiveness of the technically feasible options.³⁰ A brief description of each step is provided below.

Step 1 - Identify All Available Control Options

Available control options are those air pollution control technologies with a practical potential for application to the emission unit and the regulated pollutant under evaluation. Air pollution control technologies can include a wide variety of available methods, systems, and techniques for control of the affected pollutant, and include not only existing controls for the source category but also take into account technology transfer of controls that have been applied to similar source categories and gas streams. Technologies which have not been applied to (or permitted for) full scale operations need not be considered as available.³¹

In an effort to identify all potentially available emission control technologies, S&L searched a broad range of information sources including, but not necessarily limited to:

- EPA's RACT/BACT/LAER Clearinghouse (RBLC);
- EPA's New Source Review (NSR) and Clean Air Technology Center (CATC) Web sites;
- BART evaluations prepared during the initial Regional Haze planning period;
- Information from control technology vendors and engineering/environmental consultants;
- Federal and State NSR permits and BACT determinations for similar sources; and
- Technical journals, reports, newsletters and air pollution control seminars.

Step 2 - Eliminate Technically Infeasible Control Options

In Step 2, S&L evaluated the technical feasibility of the control options identified in Step 1 with respect to source-specific and unit-specific factors. Control technologies are technically feasible if either: (1) they have been installed and operated successfully for the type of source under review under similar conditions; or (2) the technology could be applied to the source under review. In order for a control option to be technically feasible, it

³⁰ See, 40 CFR Part 51 Appendix Y, Section IV.D.

³¹ *Id.*, at IV.D.1.

must be “available” and “applicable” to the source under consideration. A technology is considered “available” if the source owner may obtain it through commercial channels. An available technology is “applicable” if it can reasonably be installed and operated on the source type under consideration.³²

Control technologies that are technically infeasible (i.e., not available or not applicable to the source under consideration) are eliminated for further evaluation. A demonstration of technical infeasibility must be based on physical, chemical and engineering principals, and must show that technical difficulties would preclude the successful use of the control option on the emission unit under consideration. The economics of an option are not considered in the determination of technical feasibility/infeasibility.

Step 3 - Evaluate Technically Feasible Control Technologies for Effectiveness

Step 3 involves evaluating the control effectiveness of all the technically feasible control alternatives identified in Step 2 for the pollutant and emissions unit under review. Control effectiveness should be expressed using a metric that ensures an “apples-to-apples” comparison of emissions performance levels among options, and is generally expressed as the rate that a pollutant is emitted after installation of the control measure. Control technology evaluations for existing sources should consider ways to improve the performance of existing control devices. Special circumstances pertinent to the specific source under review should be identified and taken into consideration when assessing the capability of the control alternative and determining control effectiveness.

For this evaluation, S&L assessed the technically feasible SO₂ and NO_x control options for effectiveness on AVS Units 1 and 2. As discussed above, AVS Units 1 and 2 are PC tangential-fired boilers designed to fire North Dakota lignite. The units are equipped with SOFA, LNCFS and an Omnivise Combustion Optimizer for NO_x control, DFGD and FF for SO₂ and PM control.

³² A more detailed description of control technology “availability” and “applicability” is provided in 40 CFR Part 51 Appendix Y, Section IV.D.2.
SL-014754_AVIS_Four-Factor Analysis_Final.docx
Project 13772-001

4. SO₂ CONTROL EVALUATION

4.1 BASELINE SO₂ EMISSIONS

The first step in developing the four factor analysis is to establish AVS Units 1 and 2 baseline SO₂ emissions. To establish representative baseline emissions, S&L evaluated AVS Units 1 and 2 operating data for the five year period January 1, 2013 to June 30, 2018 to identify periods of normal operation (i.e., periods of operation when the boiler was not limited by infrequent or extraordinary operating restrictions). Based on review of fuels consumed, heat input to the boiler, boiler heat rates, power generation, and capacity factors, as well as input from Basin Electric, it was determined that the operating periods of January 1, 2013 to June 30, 2018 were representative of normal boiler operation for SO₂ emissions. The representative baseline periods for the AVS Units are shown in Table 4-1.

Table 4-1. Representative Baseline Periods for SO₂ Emissions

Pollutant	Representative Baseline Periods	
	AVS Unit 1	AVS Unit 2
SO ₂ Emissions	1/1/2013 to 6/30/2018	1/1/2013 to 6/30/2018

Baseline annual SO₂ emissions were determined based on data obtained from the Units 1 and 2 continuous emissions monitoring system (CEMS) that was reported to EPA's Clean Air Markets. The maximum 24-consecutive month annual average emission rate during the representative time period was used to establish baseline annual emissions (in terms of tons per year). Representative baseline emission factors (in terms of pounds per million British Thermal Units (lb/MMBtu)) were developed using baseline annual emissions and the respective annual heat inputs. Table 4-2 provides a summary of the AVS Units 1 and 2 SO₂ representative baseline emissions; additional details are included in Appendix B. Table 4-3 provides a summary of the AVS Units 1 and 2 SO₂ projected future maximum emissions based on the future projected coal sulfur content, boiler design heat input and 100% capacity factor.

Table 4-2. Baseline Actual SO₂ Emissions

AVS Unit	Baseline Controls	SO ₂ Emission ^(Notes 1 and 2)			Capacity Factor During Baseline Period	Current SO ₂ Control Percentage ^(Note 3)	Current Permit Limits (3-hr rolling average)
		lb/hr	lb/MMBtu	tons/yr			
Unit 1	DFGD/FF	1,656	0.37	6,921	86%	86-88	1.2 lb/MMBtu 3,845 lb/hr (plant total)
Unit 2	DFGD/FF	1,685	0.37	7,016	87%	86-88	1.2 lb/MMBtu 3,845 lb/hr (plant total)

Note 1. Unit 1 SO₂ emissions based on 24-month annual average for period September 2014 to August 2016.

Note 2. Unit 2 SO₂ emissions based on 24-month annual average for period July 2016 to June 2018.

Note 3. Control percentage calculated based on the range of baseline annual coal SO₂ content (2.72 – 3.15 lb/MMBtu) between 2013-2018.

Table 4-3. Projected Future Maximum SO₂ Emissions

AVS Unit	Baseline Controls	SO ₂ Emission ^(Note 1)			Capacity Factor for Future Maximum Emissions	Assumed SO ₂ Control Percentage ^(Note 2)	Current Permit Limits (3-hr rolling average)
		lb/hr	lb/MMBtu	tons/yr			
Unit 1	DFGD/FF	1,831	0.37	8,018	100%	89.1	1.2 lb/MMBtu 3,845 lb/hr (plant total)
Unit 2	DFGD/FF	1,847	0.37	8,089	100%	89.1	1.2 lb/MMBtu 3,845 lb/hr (plant total)

Note 1. Projected future maximum SO₂ emissions based on forecast future maximum coal SO₂ content of 3.39 lb/MMBtu, boiler design heat input of 4,930 MBtu/hr and assumes 100% capacity factor.

Note 2. Control percentage calculated based on the baseline SO₂ emission rate of 0.37 lb/MMBtu and the baseline average uncontrolled emission rate of 3.39 lb/MMBtu.

4.2 COAL SULFUR CONTENT

The generation of SO₂ is directly related to the sulfur content and heating value (HHV) of the fuel burned. AVS currently burns North Dakota Lignite fuel from the Freedom Mine. North Dakota lignite is characterized by a low heating value and relatively low sulfur content. Typical HHV and coal sulfur content provided by Basin Electric are listed in Table 4-4. The coal quality is based on actual annual fuel data provided by the facility between 2013 and 2018, which is the same time period as the baseline emission rates.

Table 4-4. Baseline AVS Coal Quality (Annual)

Parameter	Minimum	Average	Maximum
HHV (Btu/lb)	6556	6755	7169
As-Received Sulfur (%)	0.89	0.98	1.13
Uncontrolled SO ₂ (lb/MMBtu)	2.72	2.90	3.15

As shown in Table 4-4, the deviation between the average coal sulfur content and the maximum coal sulfur content is 0.15%.

In addition, Basin Electric provided anticipated future annual average coal quality projections for the facility between 2019 and 2045. The future range in coal quality is provided in Table 4-5.

Table 4-5. Future AVS Coal Quality (Annual)

Parameter	Minimum	Average	Maximum
HHV (Btu/lb)	6,434	6,506	6,587
As-Received Sulfur (%)	0.72	0.84	0.94

The future projected coal quality listed in Table 4-5 are based on an annual average values and do not take into account potential deviations in the coal quality that could be seen on a short term basis. As such, S&L and Basin Electric applied the actual coal sulfur content deviation (0.15%) from the baseline coal quality, stated above, to the maximum annual sulfur coal in Table 4-5. The results are shown in Table 4-6.

Table 4-6. Design Basis for Future Projected AVS Coal Quality (Annual)

Parameter	Value
HHV (Btu/lb)	6,434
As-Received Sulfur (%)	1.09
Uncontrolled SO ₂ (lb/MMBtu)	3.39
Uncontrolled SO ₂ per Unit(lb/hr) ^(Note 1)	16,704
Uncontrolled SO ₂ per Unit (ton/yr) ^(Note 1)	73,164

Note 1. Uncontrolled SO₂ emissions calculated at the design heat input (4,930 MBtu/hr) of each Unit.

Based on the evaluation above, S&L and Basin Electric have concluded that using a 3.39 lb SO₂/MMBtu as the design basis for evaluating the SO₂ control technologies presented in this report is reasonable.

4.3 SO₂ EMISSIONS CONTROLS

4.3.1 Identify Available SO₂ Control Options

Based on a review of available SO₂ control technologies, as well as operational practices and equipment upgrades implemented on existing control systems, potentially available options to control SO₂ emissions from AVS Units 1 and 2 are listed in Table 4-7.

Table 4-7. Available SO₂ Control Options

SO ₂ Control Technologies
Fuel Switching
Existing DFGD Operational Improvements
Existing DFGD Upgrades
Existing DFGD + Dry DSI (DSI)
Retrofit New Dry FGD
Retrofit New Wet FGD

4.3.2 Technical Feasibility of Available SO₂ Control Options

Potentially available SO₂ control options identified in Table 4-7 are those control technologies and operational improvements with a practical potential for application to AVS Units 1 and 2. The technologies were evaluated for

technical feasibility (i.e. availability and applicability to AVS Units 1 and 2) based on a review of physical, chemical, and engineering principals, and an assessment of commercial availability. Options determined to be technically infeasible, or options that have no practical application to AVS, were eliminated from further review. S&L evaluated the effectiveness of the control options determined to be technically feasible, and established an emissions performance level (i.e., control emissions rate) for each.

4.3.2.1 Fuel Switching

One potential strategy for reducing SO₂ emissions is to reduce the sulfur content of the coal. Limiting the amount of sulfur in the coal directly limits the amount released during the combustion process, and would reduce SO₂ loading to the dry scrubber.

AVS is a mine mouth generation facility. AVS was designed and developed to burn North Dakota lignite coal received from the adjacent Freedom Mine for the purpose of generating electricity. Previous regulatory and court decisions have concluded that requiring a mine mouth facility to evaluate low sulfur coal would require the facility to redefine its fundamental purpose and design; therefore, fuel switching can be rejected as an available control option.³³ Because the use of North Dakota lignite from the adjacent Freedom Mine is an inherent aspect of AVS operation, fuel switching will not be evaluated.

4.3.2.2 Existing FGD Operational Improvements and Equipment Upgrades

Operational and other design changes/upgrades to the existing dry scrubber may provide an opportunity for additional SO₂ removal and allow the units to achieve lower controlled SO₂ emissions. S&L, working with Basin Electric personnel, identified a number of potentially feasible operational changes that may be available to increase SO₂ removal efficiency with the existing equipment. Potentially available operational and design changes to the existing control system are summarized in Table 4-8. A detailed discussion of each of these options is provided in the following sections.

Slaker Replacement
Adding an Absorber Module
Replacing Existing Absorbers with New Absorber Modules

Station Work Practices

AVS Units 1 and 2 have a 3-hour SO₂ plantwide applicability limit (PAL) of 3,845 lb/hr in their Title V Air Permit that allows the station to adjust operation of each unit's FGD system as long as they achieve the overall plantwide limit. Historically, when one unit would be in extended major outage the station would adjust operation (i.e., decrease SO₂ removal) on the other Unit to be in compliance with the PAL. AVS schedules major maintenance outages on a tri-annual(three-year) basis. As such, the opportunity for additional reductions is available one out of every 3 years on each unit. S&L reviewed the operating practices of the two units over the period June 2015–June 2018 to determine the increase in SO₂ emissions for the unit that was not in outage.

Table 4-9 and Table 4-10 below show the increase in SO₂ emissions for both Units 1 and 2.

Table 4-9. Increased SO₂ Emissions on AVS Unit 1 (June 2015-June 2018)

Parameter	AVS Unit 1	AVS Unit 2
Average annual hours in outage on Unit 2	--	981
Average SO ₂ emissions on Unit 1 during Unit 2 outage (lb/hr)	2,394	--
Average SO ₂ emissions on Unit 1 during normal operation (lb/hr)	1,432	--
Average excess SO ₂ emissions on Unit 1 during Unit 2 outage (lb/hr)	962	--
Average excess SO₂ emissions on Unit 1 during Unit 2 outage (ton/yr)	472	--

Table 4-10. Increased SO₂ Emissions on AVS Unit 2 (June 2015-June 2018)

Parameter	AVS Unit 1	AVS Unit 2
Average annual hours in outage on Unit 1	769	--
Average SO ₂ emissions on Unit 2 during Unit 1 outage (lb/hr)	--	2,573
Average SO ₂ emissions on Unit 2 during normal operation (lb/hr)	--	1,542
Average excess SO ₂ emissions on Unit 2 during Unit 1 outage (lb/hr)	--	1,031
Average excess SO₂ emissions on Unit 2 during Unit 1 outage (ton/yr)	--	396

As shown in the tables above, the excess emission on Units 1 and 2 were 472 tons and 396 tons, respectively on an annual basis. Using the annual baseline SO₂ emissions and annual average heat input, provided in Section 4, eliminating these emissions would reduce the outlet SO₂ emission rate from 0.37 lb/MMBtu to a controlled emission rate of 0.35 lb/MMBtu on each Unit. However, it should be noted that under the current outage schedule, the emission reductions shown above would only be achieved every 3rd year for a single unit since outages occur on a tri-annual basis. Based on this analysis, a change to the current station work practice is considered a technically feasible SO₂ control option for AVS Units 1 and 2.

Lime Quality

The quantity of lime (CaO) available in a dry scrubbing system compared to the amount of SO₂ entering the system is called the stoichiometric ratio (generally referenced as the Ca:S stoichiometric ratio). Reagent quality directly affects the Ca:S stoichiometric ratio in DFGD control systems. Using a high quality lime increases the availability of hydrated lime to support process chemistry, and reduces the lime slurry injection rate needed for SO₂ removal.

Lime quality is measured both by the CaO content and reactivity of the lime product. In a dry scrubber system, CaO is combined with water in a slaker to form hydrated lime or calcium hydroxide (Ca(OH)₂), which provides the calcium that is needed to react with SO₂ in the flue gas. With a higher quality lime, more calcium hydroxide is available to react with SO₂. Lime products with a CaO content of 90% or greater are generally considered high quality lime. Reactivity of the lime is measured by the temperature rise when the lime is slaked (i.e. water addition). In general, porous lime products have higher reactivity which is demonstrated by achieving a temperature rise 40°C within three minutes of adding water.

Based on a review of lime analyses and a review of operating data from the existing lime slaking system, AVS currently procures a high quality lime for use in the dry scrubbers. The typical CaO content of the lime used at AVS is 90% or greater, and the slaking process achieves a 40°C temperature rise within three minutes of adding water. For these reasons, changing the lime quality is not considered a technically feasible operational change available to control SO₂ emissions from AVS, and will not be evaluated further.

Ca:S Stoichiometric Ratio

Other operational changes that may be available to increase the Ca:S stoichiometry in the existing dry scrubber include: (1) increasing the byproduct recycle ash rate; and/or (2) increasing the quantity of fresh hydrated lime introduced to the system. Due to the cost savings that may be realized with the first option, some facilities with existing DFGD controls have opted to increase solids recycle rates to as high as 40-50% solids to achieve an incremental increase in SO₂ reduction, if capacity was available in the byproducts handling system. If capacity is not available, increasing fresh lime addition to the system may also be a viable option to increase the Ca:S stoichiometric ratio.

Within each AVS DFGD, there are two parallel slurry preparation trains that prepare and supply the lime slurry feed to each of the five scrubber modules. The slurry preparation trains consist of recycle ash silos, ash mix tanks, slurry feed tanks and associated slurry and atomizer feed pumps, piping and controls and instrumentation. Solids

from a dry scrubber consist of fly ash, reaction byproduct, and residual unreacted hydrated lime. On AVS Units 1 and 2, solids collected in the fabric filter hoppers are conveyed to either a dry storage silo for disposal or to a recycle ash silo where it is used as reactant slurry. The recycle system is designed to utilize a portion of the unreacted lime in the solids rather than disposing of all of the solids. Recycle solids are combined with the fresh lime addition to provide the makeup lime needed for SO₂ reduction. Increasing the recycle rate can increase the amount of available Ca added to the system (i.e., stoichiometric ratio) without increasing the quantity of fresh lime added to the system.

The DFGD systems on the AVS Units currently operate the recycle system at approximately 45% solids. The AVS recycle system is operating within the original design conditions and system capacity which is in line with industry practice. The plant has tested higher recycle rates, but at these higher rates plant personnel reported significant problems with recycle slurry pumping and pluggage of the recycle tanks and negative impacts to the FF due to the increase in ash loading. Based on the adverse operational impacts observed during these tests, increasing the recycle percent solids is not considered a technically feasible SO₂ control option for the AVS Units, and will not be evaluated further.

As an alternative to increasing the recycle rate, the Ca:S stoichiometric ratio in the system may be increased by increasing the quantity of fresh lime introduced to the system. Basin Electric contracted with B&W, the original equipment manufacturer (OEM) of the AVS DFGD system, to determine if additional SO₂ removal could be achieved by increasing the amount of fresh lime added to the system while maintaining approximate 40-45% solids slurry to the atomizer. B&W ran their proprietary software which estimates the AVS DFGD performance. The results of the model indicated that AVS could potentially achieve 93% SO₂ removal of normal DFGD operation at 1% sulfur coal by increasing the fresh lime to the DFGD. Due to the uncertainties with the model, additional analysis is required to fully understand plant operational and performance impacts associated with an increased Ca:S stoichiometric ratio. There would be percent solids capacity limitation with the existing recycle slurry system and risks of increased scaling and build-up within tanks and piping with the increased lime solids. As such, this system will require modifications including new mix tanks, pumps and piping to minimize slurry preparation train outages. When a slurry preparation train fails, it requires the standby slurry preparation train to come on-line that could result in an increase in short term emissions until the slurry preparation train is placed into service. The 93% removal represents an average percent control that each AVS unit would be expected to achieve on an on-going long-term basis under normal operating conditions with the equipment upgrades installed. The emission rate should

not be construed to represent proposed permit limits. Corresponding permit limits must be evaluated on a control system-specific basis.

Approach to Saturation Temperature

The reaction of SO_2 with $\text{Ca}(\text{OH})_2$ in a dry scrubber is driven by the absorber temperature. Water surrounding the lime slurry droplet allows SO_2 to dissolve into the liquid and facilitates the reaction between lime and SO_2 . The temperature differential between the inlet and the outlet of the DFGD is used as a driving force for SO_2 removal; however, outlet temperatures must be maintained above the saturation temperature to ensure byproducts exiting the absorber module are dry and remain dry as they pass through the FF, ductwork and stack. Residence time within the absorber vessel, drying time, and exit temperature are all important design parameters for a dry scrubbing system.

Inlet temperature to the dry scrubbing module is relatively constant; however there can be short term temperature swings of $\pm 10^\circ\text{F}$ that occur due to coal quality, boiler sootblowing, convection pass and air heater cleanliness; therefore, temperature differential across the module is a function of the outlet temperature. As a general rule-of-thumb, the closer the outlet temperature is to the adiabatic saturation temperature, the higher the SO_2 removal efficiency.

Operating a dry scrubbing system at outlet temperatures significantly above the adiabatic saturation temperature accelerates water evaporation from the reactant slurry, limits SO_2 absorption into the droplet, and limits the reaction between the lime and SO_2 . Reducing the temperature in the absorber closer to the saturation point can provide additional SO_2 removal. On the other hand, the absorber module may not have sufficient residence time to dry all slurry droplets if the system is operated too close to adiabatic saturation, which would result in deposits in the absorber module, corrosion, and severe operational problems. Therefore, maintaining an absorber outlet temperature close to the point of saturation, while staying above it, is vital for optimal reaction kinetics.

The AVS dry scrubbers currently operate with at an outlet temperature near $165\text{--}170^\circ\text{F}$, which is approximately 30°F above the adiabatic saturation temperature and within the OEM design. This is in line with new spray dryer absorbers which are typically designed to operate at 30°F approach to saturation. Therefore, the current approach to saturation temperature achieved on the AVS scrubbers are aligned with standard industry practices. Lowering the outlet temperature further has significant potential to cause detrimental corrosion of the vessel or downstream

equipment and other significant operating issues. Therefore, further reducing the absorber module outlet temperature is not considered a technically feasible SO₂ control option for AVS, and will not be evaluated further.

Atomizer Replacement

Spray droplet size is an important parameter in the design and operation of a dry scrubber, and can improve lime utilization and SO₂ removal. Finer spray will increase the surface area of the slurry droplets exposed to the flue gas. Greater surface area increases the potential for SO₂ to absorb into the moisture of the slurry droplets. Droplet fineness also plays a role in particle drying time. Larger droplets can have a negative effect on the slurry drying time which can lead to moisture carryover to downstream equipment causing buildup and corrosion.

AVS Units 1 and 2 dry scrubbers were provided by B&W's predecessor Joy Niro, and were designed with five absorber modules each with a single rotary atomizer with a 12 nozzle wheel to achieve a fine slurry spray. The design of the atomizer and speed at which the wheel rotates are controlling factors for the size and form of the droplets in the spray. Each atomizer wheel in AVS Unit 1 absorber module is powered by a 700 hp motor and Unit 2 absorber modules are designed with a 800 hp motor. In addition, the design of the atomizers is highly dependent on the spray pattern needed to mix with the hot flue gas in the scrubber module for optimum absorption of SO₂ while also preventing wetting of the absorber walls. Based on S&L's analysis and input from the station, there has not been any significant moisture carry-over into the baghouse or wetting of the absorber walls that would indicate that the atomizers are not achieving an optimum droplet size or spray pattern. In addition, both AVS dry scrubbers are operating at a consistent 30°F approach to saturation temperature, in-line with industry practice, concluding that the droplets are drying efficiently. Therefore, replacing the atomizer motor or atomizer wheel is not considered a technically feasible SO₂ control option for the AVS scrubbers, and will not be evaluated further.

Slaker Replacement

Lime slurry, the reagent used for SO₂ removal in a dry scrubber, is produced by mixing pebble lime with heated water in a slaker; this process is referred to as "slaking". The slaker is operated at an optimum water-to-lime ratio (typically between 3:1 and 6:1) to produce lime slurry by metering the amount of water and the amount of lime added to the slaker. Slakers are typically designed to produce a lime slurry between 15-20% solids. The lime slurry is added to the recycle slurry in a mix tank and then sent to the atomizer where it is sprayed into the scrubber for SO₂ removal.

In 2011, additional slaking capacity was installed at a cost of approximately \$15 million, in the form of two Vert-Mill lime slakers, lime storage and conveying systems in preparation of higher sulfur fuel deliveries. The slakers operate at a 5:1 water to lime ratio and approximately 18% solids which is in line with the design as well as industry practice. Therefore, replacing the already upgraded slaking systems is not considered a technically feasible SO₂ control option for the AVS scrubbers, and will not be evaluated further.

Adding an Absorber Module

Another option for extending the residence time within the reactor modules and increasing Ca:S contact would be to add an additional reactor module to each AVS unit. The existing system is designed with five absorber modules per unit. The system was originally designed to operate with four modules carrying full load gas flow with a standby spare available for routine maintenance. Subsequently, operation was changed so that all five modules are operated for full load gas flow. This change increased flue gas residence time in the reaction vessels from 5.0 seconds (at full load) to 6.5 seconds. More recent dry scrubbing systems have been designed with reaction vessel residence times of 10 seconds or more.

One potential option available to AVS to further increase reaction vessel residence time would be to add an additional absorber module to the existing dry scrubbing system on each unit. The number of absorber modules used in a DFGD system is dependent on multiple operating parameters, including the flue gas flow rate and SO₂ concentrations. DFGD modules are typically specified with minimum and maximum flue gas flow rates. If the absorber modules are oversized, flue gas velocities through the module can be too low, causing solids dropout inside the vessel. If the absorber modules are undersized, flue gas velocities can be too high, causing residence time to fall below recommended levels.

Dry scrubbing units that are operating at flue gas volumes significantly above the design flow rate can benefit from adding an extra module to the system. The module would be placed in parallel with the existing modules to achieve a similar pressure drop through each vessel and to ensure equal flue gas distribution to the modules. In 2006, Basin Electric hired B&W's Allen-Sherman Hoff to develop a computer model of the existing five scrubber modules to determine the impact of adding a 6th absorber module to each of the AVS units in response to potentially higher-sulfur fuels in the future. The modeling showed the five existing absorbers have adequate residence time for the expected higher sulfur in the coal and operate at an approach to saturation of 30°F which is consistent with industry practice. Installation of a sixth absorber would not provide any significant improvement towards removing additional sulfur. The primary benefit of a sixth SDA chamber would be to provide redundancy. While this would

be beneficial towards maintaining unit loads without having to restrict generating capacity for chamber maintenance items, inspections and chamber cleaning, it would not provide any additional improvement to reducing SO₂. Therefore, incorporating an additional absorber module into the existing system is not a technically feasible SO₂ control strategy for AVS, and will not be evaluated further.

Replacing Existing Absorbers with New Absorber Modules

Replacing the existing modules with new absorber modules would require significant engineering and facility modifications. Based on a preliminary review of the control system layout, the only practical location for this option would be to construct the new vessels in the same location as the existing modules. Locating the DFGD modules adjacent to the existing dry scrubber would require flue gas to be redirected from the air heater outlet to the new absorbers and back to the existing fabric filter, which would likely result in significant solids dropout and other operational issues. Therefore, locating the new absorber modules adjacent to the existing absorber modules is not considered a technically feasible option.

DFGD control systems use a hydrated lime slurry to remove SO₂ from the combustion gases. Various operating parameters will affect the efficiency of the DFGD process including the residence time and how close the system operates to saturation. These are the same operating parameters that affect the efficiency of the existing AVS Units 1 and 2 dry scrubbers. The AVS Units 1 and 2 dry scrubbers already operate at an approach to saturation temperature of 30°F which is consistent with industry practice as well as have adequate residence time. Therefore, replacing the existing absorber modules with new absorber modules would not provide any additional benefit and will not be evaluated further.

4.3.2.3 Existing FGD + Dry DSI

Alkali based DSI is a proven technology for the removal of sulfur trioxide (SO₃) and other acid gases from coal-fired power plant flue gas, and can be used to provide SO₂ control. Sorbent is injected into the ductwork after the furnace and prior to the particulate collection device, where it reacts with SO₂ and other acid gases. DSI systems are relatively simple systems consisting of material storage, feeding mechanism, blower or transfer line, and an injection device. For SO₂ control on AVS Units 1 and 2, sorbent would be injected upstream of the dry scrubber to provide an incremental reduction in the concentration of SO₂ in the flue gas at the inlet to the dry scrubber.

Sorbents react with SO₂, and other acid gases, in the flue gas when injected at an appropriate rate and within the proper temperature range for that sorbent. The resulting particulate matter is removed from the flue gas by the

particulate control system. The process works through neutralization of the acid gases with the alkaline sorbent. The neutralization reaction occurs as long as the sorbent remains in contact with the gas in the flue gas duct work within the required temperature range.

Dry sorbents that have been used for SO₂ control on coal-fired boilers include:

- Hydrated Lime (Ca(OH)₂)
- Trona or Sodium Bicarbonate (SBC)

The following wet sorbents have also been used for acid gas control at coal-fired power generating stations:

- Sodium Bisulfite (SBS)
- Soda Ash

Dry sorbents, including hydrated lime, Trona, and SBC would be injected pneumatically as a dry powder into the flue gas ductwork upstream of the AVS Units 1 and 2 DFGD. Trona and SBC are both sodium-based sorbents, which react with SO₂ to form sodium salts. Hydrated lime would react with SO₂ to form calcium sulfate salts. The hydrated lime reactions are the same reactions that are taking place in the existing dry scrubber.

Hydrated lime is less reactive than the sodium based dry sorbents; thus, higher injection rates and longer residence time would be required to achieve the same removal efficiency. However, hydrated lime has a lower unit cost compared to other sorbent options, offsetting the higher injection rates. It is also important to note that the hydrated lime chemistry involves the same reactions, and forms the same calcium salts, as those currently taking place in the dry scrubber reaction vessels. Therefore, using hydrated lime as the sorbent would not introduce any new constituents into the dry scrubbing system, and could potentially increase the Ca:S stoichiometry in the dry scrubber.

Because of the higher reactivity of sodium based sorbents, less reactant may be required to achieve the same removal efficiency; however, injecting a sodium-based sorbent into the flue gas upstream of the AVS Units 1 and 2 DFGD would introduce new chemical constituents into the scrubber and into the fly ash/scrubber byproduct material. This could prove problematic as sodium compounds are water soluble, and introducing sodium into the system could adversely affect the characteristics of the byproduct solids generated by the system and introduce additional corrosion related issues within the SDA and FF systems. Detailed studies and demonstration tests would be needed to ensure that introducing relatively large amounts of sodium would not adversely affect scrubber operation or result in solids disposal issues.

SBS and soda ash (Na_2CO_3) injection are wet injection technologies typically used for SO_3 mitigation. SBS and soda ash can be injected into the flue gas upstream or downstream of the air heater as a 10% solution (by weight) using dual fluid atomizers. Both products will react with SO_2 and SO_3 to form sodium salts, which can be collected in the downstream particulate collection device. URS/Codan Associates own the patent for this SBS control process. Based on conversations with URS, their SBS technology is generally more economical using soda ash, and all recent projects have used soda ash. However, as with the dry sodium-based injection systems, these systems would introduce sodium into the AVS Units 1 and 2 DFGD control system.

DSI upstream of the existing dry scrubber is a technically feasible and commercially available SO_2 control option for AVS Units 1 and 2. Taking into consideration the fact that AVS is currently equipped with a calcium-based dry scrubbing system, hydrated lime dry DSI would be the most practical, and potentially the most effective, DSI control option. Sodium-based systems would require extensive testing to determine the potential impacts associated with introducing significant quantities of sodium into the existing system, and are not considered practical control options for AVS Units 1 and 2. However, although DSI is a technically feasible control option, it should be noted that DSI upstream of the existing DFGD control system at AVS would not provide any additional SO_2 removal than what could already be achieved by increasing the fresh lime or calcium content through the existing upgraded lime slaking system as discussed in Section 4.3.2.2 Ca:S Stoichiometric Ratio. The existing upgraded lime slaking system at AVS has sufficient capacity to provide the increase in calcium content. Therefore, DSI will not be evaluated further.

4.3.2.4 Retrofit New Dry FGD System

Replacing the existing dry scrubber/FF with new control systems would require significant engineering and modifications to the facility. Based on a preliminary review of the facility layout, the new control systems could be located south of Unit 1 and north of the Unit 2 existing dry scrubber/FF. The new DFGD/FF and all auxiliary equipment could be constructed while the units remain on line. The control systems could be tied-in to the existing systems during a scheduled major outage.

Various DFGD systems have been designed for use with pulverized coal-fired boilers; including the SDA and circulating dry scrubber (CDS). Both systems are evaluated in more detail below.

Spray Dryer Absorber / Fabric Filter

SDA systems have been used in large coal-fired utility applications, and have demonstrated the ability to effectively reduce uncontrolled SO₂ emissions from pulverized coal units. Like other dry scrubbing systems, SDA control systems use a slurry of lime and water injected into the reaction modules to remove SO₂ from the combustion gases. The reaction modules are designed to provide adequate contact and residence time between the exhaust gas and the slurry to produce a dry by-product. Process equipment associated with an SDA control system includes an alkaline storage tank, mixing and feed tanks, atomizer assembly, spray chamber module, integrated fabric filter, and solids recycle system. The recycle system collects solid reaction byproducts and recycles them back to the spray dryer feed system to maximize reactant utilization.

Various process parameters affect the efficiency of the SDA process including: the type and quality of the additive used for the reactant, reactant-to-sulfur stoichiometric ratio, how close the SDA is operated to saturation conditions, and the amount of solids product recycled to the atomizer. SDA systems are typically designed to operate within approximately 30 °F adiabatic approach to saturation temperature. Operating closer to the adiabatic saturation temperature may allow for higher SO₂ control efficiencies; however, outlet temperatures too close to the saturation temperature will result in severe operating problems including reactant build-up in the absorber modules, blinding of the fabric filter bags, and corrosion in the fabric filter and ductwork.

SO₂ removal efficiencies in a SDA are also dependent upon good gas-to-liquid contact. Reactant spray nozzle designs are vendor-specific, and include both dual-fluid nozzles and rotary atomizers. The atomizing nozzle assembly is typically located in the SDA penthouse and flange mounted to the roof of the absorber vessel.

Replacing the existing dry scrubber/FF with a new SDA/FF control systems is a technically feasible and commercially available control option on the AVS Units. SDA/FF control systems are generally limited to an SO₂ removal of approximately 95%. This removal represents what the control system vendor would be willing to guarantee upon initial operation of the control system.

Circulating Dry Scrubber / Fabric Filter

A second type of dry scrubbing system is the circulating dry scrubber (CDS). Similar to other DFGD systems, the CDS system would be located after the air preheater, and byproducts from the system collected in an integrated fabric filter. Unlike the SDA systems, CDS systems use a circulating fluidized bed of hydrated lime reagent to

remove SO₂ rather than an atomized lime slurry; however, similar chemical reaction kinetics are used in the SO₂ removal process.

In a CDS, flue gas is treated in an absorber vessel where the flue gas stream flows through a fluidized bed of hydrated lime and recycled byproduct. Water is injected into the absorber through a venturi located at the base of the absorber for temperature control. Flue gas velocity through the vessel is maintained to keep the fluidized bed of particles suspended in the absorber. Water sprayed into the absorber cools the flue gas from approximately 300 °F at the inlet to the scrubber to approximately 160 °F at the outlet of the fabric filter. The hydrated lime absorbs SO₂ from the gas and forms calcium sulfite and calcium sulfate solids. Desulfurized flue gas passes out of the absorber, along with the particulate matter (reaction products, unreacted hydrated lime, calcium carbonate, and the fly ash) to the fabric filter.

As with the SDA/FF option, replacing the existing DFGD with a new CDS/FF control system would require significant engineering and modifications to the existing facility. For this evaluation it was assumed that the CDS/FF control systems could be located adjacent to the existing dry scrubber/FF, and that the control systems could be tied-in to the existing system during a scheduled major outage.

Replacing the existing dry scrubber and FF with a new CDS/FF control system is a technically feasible and commercially available control option for the AVS units. Based on engineering judgment, it is anticipated that the retrofit CDS/FF control option would achieve controlled SO₂ emission rates higher than those achieved with a SDA/FF due to the increased Ca:S in the fluidized bed absorber vessel. Based on recent CDS retrofit projects, and taking into consideration expected future design coal characteristics, it is anticipated that the retrofit CDS/FF control system could achieve SO₂ removal efficiencies of approximately 97%. This removal efficiency represents what the control system vendor would be willing to guarantee upon initial operation of the system and on an on-going long-term basis under normal operating conditions.

4.3.2.5 Retrofit New Wet FGD System

Another option available to AVS would be to replace the existing dry scrubbing system with a new wet FGD control system located downstream of the existing FF.

Wet FGD technology is an established SO₂ control technology. Wet scrubbing systems have been designed to utilize various alkaline scrubbing solutions including lime, limestone, and magnesium-enhanced lime. Wet

scrubbing systems have also been designed with spray tower reactors and with reaction vessels (e.g., jet bubbling reactor). Although the flue gas/reactant contact systems may vary, the chemistry involved in all wet scrubbing systems is essentially identical. All wet scrubbing systems use an alkaline slurry that reacts with SO_2 in the flue gas to form insoluble calcium sulfite (CaSO_3) and calcium sulfate (CaSO_4) salts.

A large majority of the wet FGD systems designed to remove SO_2 from existing high-sulfur utility boilers have been designed as wet limestone scrubbers with spray towers and forced oxidation systems. Therefore, for this evaluation, it was assumed that the WFGD control system would be designed as a limestone spray tower scrubber with forced oxidation. Other potentially available wet scrubber designs are not included in this evaluation because the chemistry involved in all wet scrubbing systems are essentially identical, alternative designs would not provide any additional SO_2 control, and control system costs would be similar.

Wet Limestone Scrubbing

In a wet limestone scrubbing system, limestone (CaCO_3) is mixed with water to formulate the alkali scrubber slurry. Flue gas enters the absorber vessel and contacts the absorbent slurry in a countercurrent spray tower. SO_2 in the flue gas reacts with the limestone slurry to form insoluble calcium sulfite (CaSO_3) and calcium sulfate (CaSO_4) which is removed as a solid waste by-product. Spent absorbent is returned to the reaction tank where dissolved sulfur compounds are precipitated as calcium salts. Fresh limestone slurry is added to regenerate the spent absorbent.

The reaction tank is sized to provide sufficient time for precipitation of the sulfur compounds. From the reaction tank, regenerated absorbent slurry is recycled to the absorber. The slurry typically contains from 5 to 15% suspended solids consisting of fresh additive, absorption reaction products, and lesser amounts of fly ash. To regulate the accumulation of solids, a bleed stream from the reaction is routed to the solid/liquid separation equipment.

Forced oxidation of the scrubber slurry may be used with limestone WFGD systems to produce calcium sulfate solids (gypsum) instead of the calcium sulfite by-product. Air blown into the reaction tank provides oxygen to convert most of the calcium sulfite (CaSO_3) to relatively pure gypsum. Forced oxidation of the scrubber slurry provides a more stable by-product and reduces the potential for scaling in the spray tower. The gypsum by-product from this process must be dewatered, and may be salable if a local market for gypsum is available, reducing the quantity of solid waste that needs to be landfilled.

For this evaluation it was assumed that the existing AVS dry scrubber reactor vessel would remain in place, and that the WFGD control system would be located downstream of the existing FFs and ID fans most likely south of Unit 1 and north of the Unit 2 existing dry scrubber/FF. Dry scrubber reactor vessel internals would ultimately be removed to reduce pressure drop through the system. A single absorber tower for each Unit would be sufficient for the flue gas flow. In addition to the absorber tower and reaction vessel, the WFGD control system would require a limestone handling and preparation system and by-product dewatering systems. Because of the saturated nature of the flue gas exiting the WFGD and the velocity requirements with wet stack operation, a new stack with a liner capable of wet flue gas operation would be required. New booster ID fans would also be required to account for the additional pressure drop through the WFGD control system.

Wet FGD technology is an established SO₂ control technology. Wet scrubbing systems have been installed on units that fire medium to high sulfur coals, and would be a technically feasible SO₂ control option for AVS Units 1 and 2. Based on engineering judgment and information from control system vendors, it is anticipated that a retrofit WFGD control system on a North Dakota lignite-fired unit would be designed to achieve and SO₂ removal efficiency of approximately 98%. This removal efficiency represents what the control system vendor would be willing to guarantee upon initial operation of the system and on an on-going long-term basis under normal operating conditions.

4.3.2.6 Technical Feasibility Summary

Table 4-11 summarizes the results of the feasibility evaluation of available control options for AVS Units 1 and 2.

Table 4-11. Technically Feasible SO₂ Control Options

SO ₂ Control Option	Technically Feasible (Yes/No)	Control Percentage (Note 1)	Technical Feasibility Summary
Fuel Switching	No	0%	Fuel switching is not considered an available SO ₂ control option for AVS Units 1 and 2 since the units are mine mouth to the existing source of lignite coal.
Existing DFGD Operational Improvements:			
Station Work Practice	Yes	5%	Adjusting operation on the non-outage unit to maintain the same SO ₂ removal efficiency achieved prior to the other Unit taking an outage is considered a technically feasible option for AVS Units 1 and 2. However, the opportunity to achieve these reductions is one out of every three years on each unit
Lime Quality	No	0%	Changing lime quality in the existing DFGD control system is not a technically feasible operational change for AVS Units 1 and 2.
Ca:S Stoichiometric Ratio	Yes	93%	Increasing the Ca:S stoichiometric ratio by increase the quantity of fresh lime to the system is considered a technically feasible option for AVS Units 1 and 2.
Approach to Saturation Temperature	No	0%	Further reducing the absorber module outlet temperature on the existing DFGD control system is not a technically feasible option for AVS Units 1 and 2.
Existing DFGD Equipment Upgrades:			
Atomizer Replacement	No	0%	Replacing the existing atomizers is not a technically feasible option for AVS Units 1 and 2.
Slaker Replacement	No	0%	Slaker replacement would not be expected to provide additional SO ₂ control, and is not a technically feasible equipment upgrade for AVS Units 1 and 2.
Adding an Absorber Module	No	0%	Adding an absorber module to AVS Units 1 and 2 is not a technically feasible SO ₂ control option.
Replace Existing Absorbers with New Absorber Modules	No	0%	Replacing the exiting absorber modules with new absorber modules is not a feasible SO ₂ control system upgrade for AVS Units 1 and 2 since it would require at least a 12-month outage and replacement power, existing today, is not available.
Existing DFGD + DSI	Yes	0%	Hydrated lime DSI upstream of the existing AVS Units 1 and 2 absorber modules is a technically feasible SO ₂ control option, however would not be expected to provide any additional SO ₂ control beyond what could be achieved with increasing the Ca:S stoichiometric ratio through the existing lime slaking system.
New Retrofit DFGD (CDS/FF)	Yes	97%	Replacing the existing DFGD control system with a new retrofit DFGD (i.e., CDS/FF) is a technically feasible SO ₂ control option for AVS Units 1 and 2.

SO ₂ Control Option	Technically Feasible (Yes/No)	Control Percentage (Note 1)	Technical Feasibility Summary
New Retrofit WFGD	Yes	98%	Replacing the existing DFGD control system with a new retrofit WFGD is a technically feasible SO ₂ control option for AVS Units 1 and 2.

Note 1. Control percentage calculated using the baseline SO₂ coal quality of 2.90 lb/MBtu and the achievable SO₂ emission rate for each technically feasible control option.

4.3.3 Evaluate Technically Feasible SO₂ Control Options for Effectiveness

The technically feasible SO₂ control technologies for Units 1 and 2 are listed in Table 4-12 and Table 4-13 in increasing order of control efficiency. Table 4-12 and Table 4-13 also provide control option-specific SO₂ emission rates in terms of lb/MMBtu. Emission rates shown represent baseline average emission rates that the control options would be expected to achieve during normal operations.

Table 4-12. Evaluate Technically Feasible SO₂ Control Options by Effectiveness for AVS Unit 1 (Baseline Average Emissions)

Alt. No.	Control Technology	SO ₂ Emission Rate (Note 1) lb/MMBtu	% Reduction from Baseline SO ₂ Coal Quality (Note 2)	SO ₂ Emission Rate (Note 1) lb/hr	SO ₂ Emission Rate (Note 1) tons/yr
E	New Retrofit WFGD	0.07	98%	312	1,305
D	New Retrofit DFGD (CDS/FF)	0.09	97%	401	1,678
C	New Retrofit DFGD (SDA/FF)	0.15	95%	669	2,796
B	FGD Operational Improvements – Increase Ca:S Stoichiometric Ratio	0.20	93%	892	3,728
A	FGD Operational Improvements – Station Work Practice (Note 3)	0.35	88%	1,561	6,524
--	Baseline (existing DFGD/FF)	0.37	87%	1,656	6,921
--	Permit Limit (assumes 50/50 split for each unit)	1.2 (3-hour)		1,923 (3-hour)	

Note 1: Emission rates shown represent average emission rates that the control options would be expected to achieve on an on-going long-term basis under normal operating conditions for AVS Unit 1. Emission rates are provided for comparative purposes, and should not be construed to represent proposed permit limits. Corresponding permit limits must be evaluated on a control system-specific basis.

Note 2: Baseline SO₂ coal quality is 2.90 lb/MMBtu. See Section 4.2 for additional details on coal sulfur.

Note 3: Emission reductions achievable, under the current outage schedule, would only be achieved once every three years on each Unit.

**Table 4-13. Evaluate Technically Feasible SO₂ Control Options by Effectiveness for AVS Unit 2
 (Baseline Average Emissions)**

Alt. No.	Control Technology	SO ₂ Emission Rate ^(Note 1) lb/MMBtu	% Reduction from Baseline SO ₂ Coal Quality ^(Note 2)	SO ₂ Emission Rate ^(Note 1) lb/hr	SO ₂ Emission Rate ^(Note 1) tons/yr
E	New Retrofit WFGD	0.07	98%	315	1,311
D	New Retrofit DFGD (CDS/FF)	0.09	97%	405	1,686
C	New Retrofit DFGD (SDA/FF)	0.15	95%	675	2,810
B	FGD Operational Improvements – Increase Ca:S Stoichiometric Ratio	0.20	93%	900	3,746
A	FGD Operational Improvements – Station Work Practice ^(Note 3)	0.35	88%	1,575	6,555
--	Baseline (existing DFGD/FF)	0.37	87%	1,685	7,016
--	Permit Limit (assumes 50/50 split for each unit)	1.2 (3-hour)		1,923 (3-hour)	

Note 1: Emission rates shown represent average emission rates that the control options would be expected to achieve on an on-going long-term basis under normal operating conditions for AVS Unit 2. Emission rates are provided for comparative purposes, and should not be construed to represent proposed permit limits. Corresponding permit limits must be evaluated on a control system-specific basis.

Note 2: Baseline SO₂ coal quality is 2.90 lb/MMBtu. See Section 4.2 for additional details on coal sulfur.

Note 3: Emission reductions achievable, under the current outage schedule, would only be achieved once every three years on each Unit.

Table 4-14 provides control option-specific SO₂ emission rates in terms of lb/MMBtu based on the projected future maximum emission rates. Emission rates shown represent the projected future maximum emission rates that the control options would be expected to achieve during normal operations.

**Table 4-14. Evaluate Technically Feasible SO₂ Control Options by Effectiveness – AVS Unit 1 or 2
(Projected Future Maximum Emissions)**

Alt. No.	Control Technology	SO ₂ Emission Rate ^(Note 4) lb/MMBtu	% Reduction from Future SO ₂ Coal Quality ^(Note 1)	SO ₂ Emission Rate ^(Note 1) lb/hr	SO ₂ Emission Rate ^(Note 2) tons/yr
E	New Retrofit WFGD	0.07	98%	334	1,463
D	New Retrofit DFGD (CDS/FF)	0.10	97%	501	2,195
C	New Retrofit DFGD (SDA/FF)	0.17	95%	838	3,671
B	FGD Operational Improvements – Increase Ca:S Stoichiometric Ratio	0.24	93%	1,169	5,121
A	FGD Operational Improvements – Station Work Practice ^(Note 3)	0.34	90%	1,670	7,316
--	Baseline Unit 1 (existing DFGD/FF)	0.37	89%	1,831	8,018
--	Baseline Unit 2 (existing DFGD/FF)	0.37	89%	1,847	8,089
--	Permit Limit (assumes 50/50 split for each unit)	1.2 (3-hour)		1,923 (3-hour)	

Note 1. Future SO₂ coal quality is 3.39 lb/MMBtu. See Section 4.2 for additional details on coal sulfur.

Note 2. Annual SO₂ emissions based on 8,760 hours per year operation.

Note 3: Emission reductions achievable, under the current outage schedule, would only be achieved once every three years on each Unit.

Note 4. Emission rates are provided for comparative purposes, and should not be construed to represent proposed emission limits. Corresponding permit limits must be evaluated on a control system-specific basis.

4.4 SO₂ COST OF COMPLIANCE (STATUTORY FACTOR ONE)

The economic analysis performed as part of the four factor analysis examines the cost-effectiveness of each technically feasible control technology, on a dollar per ton of pollutant removed basis. Annual emissions, calculated for a particular control device, are subtracted from baseline annual emissions to calculate tons of pollutant controlled per year. For units with existing controls, the base case represents existing baseline actual emissions. Annual costs for each control option are calculated relative to the base case by adding annual O&M costs to the annualized cost of capital and, if applicable, lost revenue due to extended outage required for installation of control equipment. Capital costs and lost revenues were annualized using a capital recovery factor based on an annual interest rate of 5.25% and equipment life of 20 years.³⁴ Cost effectiveness (\$/ton) of a particular

³⁴ The assumed 20-year equipment life is consistent with the control system equipment life used by NDDH in its evaluation of NO_x and SO₂ control technologies for BART-eligible sources. (see, e.g., ND Regional Haze Final SIP, Appendix C.1, "BART Determination Study for Leland Olds Station Units 1 & 2, Basin Electric Power Cooperative, August 2006, pgs. 64 (NO_x controls) and 158 (SO₂ controls). See also, ND

control option is simply the annual cost (\$/yr) divided by the annual reduction in annual emissions (ton/yr). In addition to cost-effectiveness relative to the base case, the incremental cost-effectiveness to go from one level of control to the next, more stringent, level of control may also be calculated to evaluate the incremental cost effectiveness of the more stringent control.

Capital and O&M cost estimates were developed for each of the technically feasible SO₂ control options. The AVS Units 1 and 2 cost estimates are conceptual in nature; thus, S&L did not procure equipment quotes specifically for the Units 1 and 2 control system upgrades. Rather, equipment costs are based on conceptual designs developed for the retrofit control systems, preliminary equipment sizing developed for the major pieces of equipment (based on AVS-specific design parameters, including typical fuel characteristics, full load heat input, and flue gas temperatures and flow rates), and recent pricing for similar equipment. S&L would characterize the cost estimates for the AVS Units 1 and 2 retrofit technologies as “concept screening” cost estimates generally based on parametric models, judgment, or analogy.

Control technology equipment costs for the retrofit options were developed by scaling cost estimates prepared by S&L for other similar projects. Major equipment costs were developed based on equipment costs recently developed for similar projects, and include the equipment, material, labor, and all other direct costs needed to retrofit the units with the control technology. Sub-accounts for the capital cost estimates (e.g., mobilization and demobilization, consumables, Contractor G&A expense, freight on materials, etc.) were developed by applying ratios from detailed cost estimates that were prepared for projects with similar scopes.

Fixed O&M costs include operating labor, maintenance labor, maintenance material, and administrative labor. Variable O&M costs include the cost of consumables, including reagent, water consumption, and auxiliary power requirements. Auxiliary power requirements reflect the additional power requirements associated with the operation of the new control technology (compared to the existing technology). All O&M costs reflect the incremental increase in O&M costs compared to the costs incurred to operate the existing dry scrubber and FF control systems.

In addition to the cost effectiveness relative to the base case, the incremental cost-effectiveness to go from one level of control to the next more stringent level of control will also be calculated to evaluate the cost effectiveness of the more stringent control.

4.4.1 SO₂ Average Annual Economic Evaluation

Table 4-15 presents the capital costs and annual operating costs associated with installing and operating each technically feasible SO₂ control system for AVS Units 1 and 2.

Table 4-16 shows the average annual and incremental cost effectiveness for each control system. Additional cost details are provided in Appendix C.

Cost estimates were not prepared for the SDA/FF option since the capital and operating costs for the SDA/FF option would be similar to the costs for the CDS/FF option, and the CDS/FF option would likely provide the opportunity to achieve somewhat lower controlled SO₂ emissions (compared to SDA/FF). Therefore, of the two new DFGD system options, only the CDS/FF option was evaluated.

Table 4-15. SO₂ Control Cost Summary (Average Annual)

AVS Unit No.	Alt. No.	SO ₂ Control Option	Total Capital Investment \$	Annual Capital Recovery Cost \$/yr	Annual Operating Cost \$/yr (Note 1)	Total Annual Cost \$/yr
Unit 1	E	Retrofit New Wet FGD	\$272,384,000	\$22,322,000	\$16,945,000	\$39,267,000
	D	Retrofit New Dry FGD (CDS + FF)	\$230,447,000	\$18,886,000	\$16,718,000	\$35,604,000
	B	Existing FGD Operational Improvements – Increase Ca:S Stoichiometric Ratio	\$9,698,000	\$795,000	\$1,144,000	\$1,939,000
	A	Existing FGD Operational Improvements – Station Work Practice	\$0	\$0	\$135,000	\$135,000
Unit 2	E	Retrofit New Wet FGD	\$272,384,000	\$22,322,000	\$16,819,000	\$39,141,000
	D	Retrofit New Dry FGD (CDS + FF)	\$230,447,000	\$18,886,000	\$16,678,000	\$35,564,000
	B	Existing FGD Operational Improvements – Increase Ca:S Stoichiometric Ratio	\$9,698,000	\$795,000	\$1,142,000	\$1,937,000
	A	Existing FGD Operational Improvements – Station Work Practice	\$0	\$0	\$131,000	\$131,000

Note 1. Annual operating costs based on baseline SO₂ coal quality (2.90 lb/MBtu) and capacity factor during baseline SO₂ period for each AVS Unit.

Table 4-16. SO₂ Emissions Control System Cost Effectiveness (Average Annual)

AVS Unit No.	Alt. No.	SO ₂ Control Option	Total Annual Cost \$	Expected Emission Reduction (Note 2) tons SO ₂ /yr	Average Annual Cost-Effectiveness (Note 2) \$/ton SO ₂ removed	Incremental Annual Cost-Effectiveness (Note 1) \$/ton SO ₂ removed
Unit 1	E	Retrofit New Wet FGD	\$39,267,000	5,616	\$6,992	\$9,826
	D	Retrofit New Dry FGD (CDS + FF)	\$35,604,000	5,243	\$6,790	\$16,420
	B	Existing FGD Operational Improvements – Increase Ca:S Stoichiometric Ratio	\$1,939,000	3,193	\$607	\$645
	A	Existing FGD Operational Improvements – Station Work Practice	\$135,000	397	\$340	--
Unit 2	E	Retrofit New Wet FGD	\$39,141,000	5,705	\$6,861	\$9,549
	D	Retrofit New Dry FGD (CDS + FF)	\$35,564,000	5,330	\$6,672	\$16,322
	B	Existing FGD Operational Improvements – Increase Ca:S Stoichiometric Ratio	\$1,937,000	3,270	\$592	\$643
	A	Existing FGD Operational Improvements – Station Work Practice	\$131,000	461	\$284	--

Note 1. Incremental cost-effectiveness represents the incremental increase in annual costs (\$/yr) divided by the incremental increase in annual SO₂ emissions reductions (tpy) between a control option and the next most effective option. For the option "Existing FGD operational improvements – Increase Ca:S Stoichiometric Ratio," incremental cost compares to the option "Existing FGD operational improvements – Station Work Practice."

Note 2. Expected emission reductions and average annual cost-effectiveness based on baseline SO₂ coal quality (2.90 lb/MBtu) and capacity factor during baseline SO₂ period for each AVS Unit.

Table 4-16 indicates that the average annual cost effectiveness of the technically feasible SO₂ control options for Unit 1 range from \$340 per ton (Existing FGD Operational Improvements – Station Work Practice) to \$6,992 per

ton (Retrofit New Wet FGD) SO₂ removed; and for Unit 2 ranges from \$284 per ton to \$6,861 per ton SO₂ removed.

The “Existing FGD operational improvements – Station Work Practice” control option is expected to achieve approximately 5% reduction from the current baseline SO₂ emissions. This option can be implemented without additional capital costs and with minimal increases in operating costs associated with increased lime use during outage periods only. The cost effectiveness of “Existing FGD Operational Improvements – Station Work Practice” control option is approximately \$300 per ton, respectively.

The “Existing FGD Operational Improvements – Increase Ca:S Stoichiometric Ratio” option would require relatively low capital investment for new tanks, pumps and piping in the slurry preparation systems since the lime slaking system had been recently upgraded, and an increase in operating costs primarily due to increased reagent usage. This option will achieve approximately 93% SO₂ reduction, resulting in a cost effectiveness of approximately \$600 per ton. It should be noted that the recent slaking upgrade project incurred a cost of \$15 million which allows the increased Ca:S stoichiometric ratio option to be viable in this analysis. Without the slaking upgrade project, the Ca:S stoichiometric ratio option would have to bear this additional cost.

The installation of new Dry FGD (CDS) or new Wet FGD systems are high capital and annual operating cost options. The cost effectiveness for these options is approximately \$6,700 per ton (Dry FGD) and \$6,900 per ton (Wet FGD). The incremental cost of installing a Dry FGD system, compared to “Existing FGD Operational Improvements – Increase Ca:S Stoichiometric Ratio,” is approximately \$16,000 per ton. The incremental cost of installing a Wet FGD system, compared to a Dry FGD system, is approximately \$10,000 per ton.

4.4.2 SO₂ Projected Future Maximum Annual Economic Evaluation

Table 4-17 presents the capital costs and annual operating costs associated with building and operating each control system; annual operating costs are based on the unit's operating at 100% capacity factor and projected future coal quality considering potential variability.

Table 4-17. SO₂ Control Cost Summary (Projected Future Maximum)

AVS Unit No.	Alt. No.	SO ₂ Control Option	Total Capital Investment \$	Annual Capital Recovery Cost \$/yr	Annual Operating Cost ^(Note 1) \$/yr	Total Annual Cost \$/yr
Unit 1	E	Retrofit New Wet FGD	\$272,384,000	\$22,322,000	\$18,361,000	\$40,683,000
	D	Retrofit New Dry FGD (CDS + FF)	\$230,447,000	\$18,886,000	\$19,993,000	\$38,879,000
	B	Existing FGD Operational Improvements – Increase Ca:S Stoichiometric Ratio	\$9,698,000	\$795,000	\$2,937,000	\$3,732,000
	A	Existing FGD Operational Improvements – Station Work Practice	\$0	\$0	\$437,000	\$437,000
Unit 2	E	Retrofit New Wet FGD	\$272,384,000	\$22,322,000	\$18,210,000	\$40,532,000
	D	Retrofit New Dry FGD (CDS + FF)	\$230,447,000	\$18,886,000	\$19,919,000	\$38,805,000
	B	Existing FGD Operational Improvements – Increase Ca:S Stoichiometric Ratio	\$9,698,000	\$795,000	\$2,932,000	\$3,727,000
	A	Existing FGD Operational Improvements – Station Work Practice	\$0	\$0	\$406,000	\$406,000

Note 1. Annual operating costs based on projected future maximum SO₂ coal quality (3.39 lb/MBtu) and 100% capacity factor for each AVS Unit.

Table 4-18 shows the average annual and incremental cost effectiveness for each control system with emissions reductions and cost effectiveness values based on 100% capacity factors and projected future maximum emission rates. Additional cost details are provided in Appendix C.

Table 4-18. SO₂ Emissions Control System Cost Effectiveness (Projected Future Maximum)

AVS Unit No.	Alt. No.	SO ₂ Control Option	Total Annual Cost \$	Expected Emission Reduction (Note 2) tons SO ₂ /yr	Average Annual Cost-Effectiveness (Note 2) \$/ton SO ₂ removed	Incremental Annual Cost-Effectiveness (Note 1) \$/ton SO ₂ removed
Unit 1	E	Retrofit New Wet FGD	\$40,683,000	6,555	\$6,207	\$2,466
	D	Retrofit New Dry FGD (CDS + FF)	\$38,879,000	5,823	\$6,677	\$12,010
	B	Existing FGD Operational Improvements – Increase Ca:S Stoichiometric Ratio	\$3,732,000	2,896	\$1,288	\$1,501
	A	Existing FGD Operational Improvements – Station Work Practice	\$437,000	702	\$623	--
Unit 2	E	Retrofit New Wet FGD	\$40,532,000	6,625	\$6,118	\$2,360
	D	Retrofit New Dry FGD (CDS + FF)	\$38,805,000	5,894	\$6,584	\$11,986
	B	Existing FGD Operational Improvements – Increase Ca:S Stoichiometric Ratio	\$3,727,000	2,967	\$1,256	\$1,513
	A	Existing FGD Operational Improvements – Station Work Practice	\$406,000	772	\$526	--

Note 1. Incremental cost-effectiveness represents the incremental increase in annual costs (\$/yr) divided by the incremental increase in annual SO₂ emissions reductions (tpy) between a control option and the next most effective option. For the option "Existing FGD operational improvements – Increase Ca:S Stoichiometric Ratio," incremental cost compares to the option "Existing FGD operational improvements – Station Work Practice."

Note 2. Expected emission reductions and average annual cost-effectiveness based on baseline SO₂ coal quality (3.39 lb/MBtu) and 100% capacity factor for each AVS Unit.

Table 4-18 indicates that the average annual cost effectiveness of the technically feasible SO₂ control options for Unit 1 range from \$623 per ton (Existing FGD operational improvements – Station Work Practice) to \$6,677 per ton (Retrofit New Dry FGD) SO₂ removed; and for Unit 2 ranges from \$526 per ton to \$6,584 per ton SO₂ removed.

The “Existing FGD Operational Improvements – Station Work Practice” control option is expected to achieve approximately 5% reduction from the current baseline SO₂ emissions once every three years on each Unit based on the current maintenance schedule. This option can be implemented without additional capital costs and with minimal increases in operating costs associated with increased lime use. The cost effectiveness of “Existing FGD operational improvements – Station Work Practice” control option is approximately \$600 per ton.

The “Existing FGD Operational Improvements – Increase Ca:S Stoichiometric Ratio” option would require the relatively low capital investment for new tanks, pumps and piping, in the slurry preparation systems since the lime slaking system had been recently upgraded, and an increase in operating costs primarily due to increased reagent usage. This option will achieve approximately 93% SO₂ removal from the projected future maximum levels, resulting in a cost effectiveness of approximately \$1,200 per ton. It should be noted that the slaking upgrade project incurred a cost of \$15 million which allows the increased Ca:S stoichiometric ratio option to be viable in this analysis. Without the slaking upgrade, the Ca:S stoichiometric ratio option would have to bear this additional cost.

The installation of new Dry FGD (CDS) or new Wet FGD systems are high capital and annual operating cost options. The cost effectiveness for these options is approximately \$6,600 per ton (Dry FGD) and \$6,200 per ton (Wet FGD). The incremental cost of installing a Dry FGD system, compared to “Existing FGD Operational Improvements – Increase Ca:S Stoichiometric Ratio,” is approximately \$12,000 per ton. The incremental cost of installing a Wet FGD system, compared to a Dry FGD system, is approximately \$2,400 per ton.

5. NO_x CONTROL EVALUATION

5.1 BASELINE NO_x EMISSIONS

The first step in developing the four factor analysis is to establish AVS Units 1 and 2 baseline NO_x emissions. To establish representative baseline emissions, S&L evaluated Units 1 and 2 operating data for the period January 1, 2013 to June 30, 2018 to identify periods of normal operation (i.e., periods of operation when the boiler was not limited by infrequent or extraordinary operating restrictions). Based on review of fuels consumed, heat input to the boiler, boiler heat rates, power generation, and capacity factors, as well as input from Basin Electric, it was determined that the operating periods of January 1, 2013 to June 30, 2018 were representative of normal plant operation. However, during the baseline period, the OFA and LNB on Units 1 and 2 were upgraded in order to comply with the First Regional Haze Planning Period. The upgraded NO_x control systems were in service and additional optimization was achieved on June 2017 (Unit 1) and July 2017 (Unit 2), by installing an Omnivise Combustion Optimizer. Thus, representative baseline periods for the AVS Units are shown in Table 5-1.

Table 5-1. Representative Baseline Periods for NO_x Emissions

Pollutant	Representative Baseline Periods	
	AVS Unit 1	AVS Unit 2
NO _x Emissions	6/1/2017 to 6/30/2018	7/1/2017 to 6/30/2018

Baseline annual NO_x emissions were determined based on data obtained from the Units 1 and 2 continuous emissions monitoring system (CEMS) that was reported to EPA's Clean Air Markets. The maximum 12-month annual average emission rates were used to establish the baseline NO_x emissions. Representative baseline emission factors (in terms of lb/MMBtu) were developed using baseline annual emissions and the respective annual heat inputs. Table 5-2 provides a summary of the AVS Units 1 and 2 NO_x representative baseline emissions; additional details are included in Appendix B. Table 5-3 provides a summary of the AVS Units 1 and 2 NO_x projected future maximum emissions based on the boiler design heat input and 100% capacity factor.

5.2 NO_x EMISSIONS CONTROLS

5.2.1 Identify Available NO_x Control Options

Based on a review of available NO_x control technologies installed on existing tangential-fired pulverized coal boilers designed to fire lignite coal, NO_x control techniques can be divided into pre-combustion strategies and post-combustion controls. NO_x control options identified for potential application to AVS Units 1 and 2 are listed in Table 5-4.

Table 5-4. Available NO_x Control Options

NO _x Control Technologies
Selective Catalytic Reduction - High Dust, Low Dust or Tail End Configuration (TE-SCR)
Selective Non-Catalytic Reduction (SNCR)
Gas Reburn
Innovative Technologies (i.e. NO _x Star, Water Injection, LoTOX, PerNO _x ide, Water Injection)

5.2.2 Technical Feasibility of Available NO_x Control Options

Potentially available NO_x control options identified in Table 5-4 were evaluated for technical feasibility (i.e. availability and applicability to AVS Units 1 and 2) based on a review of physical, chemical, and engineering principals, and an assessment of commercial availability. Options deemed to be technically infeasible, or options that have no practical application to AVS Units 1 and 2, were eliminated from further review. S&L evaluated the effectiveness of the control options determined to be technically feasible, and established an emission performance level (i.e., controlled emission rate) for each.

5.2.2.1 Selective Catalytic Reduction

SCR is a process by which ammonia (NH₃) reacts with nitric oxide (NO) and nitrogen dioxide (NO₂), collectively NO_x, in the presence of a catalyst to reduce the NO_x to nitrogen (N₂) and water (H₂O). SCR technology has been applied to NO_x-bearing flue gases generated from power generating facilities burning various types of coal, including bituminous, subbituminous, and Texas lignite). The principal reactions resulting in NO_x reduction are:

Because these reactions proceed slowly at typical boiler exit gas temperatures of a coal-fired steam electric generating unit, a catalyst is used to increase the reaction rate between NO_x and NH_3 . Depending on the specific constituents in the flue gas, a typical temperature range of 550°F to 780°F is necessary to achieve normal performance of the catalyst. For the typical coal-fired boiler, optimal performance will be in the range of approximately 650°F to 750°F.

In general, there are three candidate SCR configurations that can be employed on coal-fired steam electric generating units. The SCR configuration designations generally describe the location of the SCR reaction vessel in relation to other post-combustion air quality control systems. Candidate SCR configurations include:

- High-dust configuration
- Low-dust configuration
- Tail-end configuration

Each of these configurations is described below as they may be applied at AVS Units 1 and 2.

High-Dust Configuration

In a high-dust configuration, the SCR reactor is located in the flue gas stream between the economizer outlet and the air heater inlet. This configuration locates the SCR within the inherently optimal temperature range environment for NO_x reduction (i.e., 650°F to 750°F); however, flue gas characteristics at the economizer outlet can also have detrimental effects on the SCR catalyst. As an example, the high-dust SCR configuration exposes the SCR catalyst to high levels of fly ash loading. High levels of fly ash can result in significant erosion of the catalyst, resulting in more frequent cleaning cycles and catalyst replacement. A second major concern with the high-dust configuration at AVS Units 1 and 2 is the presence of high levels of sodium (both in the vapor-phase and as submicron aerosols) in the North Dakota lignite-derived flue gas. Sodium is a known SCR catalyst poison, and also affects the adhesive and cohesive characteristics of the fly ash, which in turn, would have an adverse effect on the SCR catalyst and reactor vessel.

SCR catalyst deactivation occurs through two primary mechanisms: physical deactivation and chemical poisoning. Physical deactivation is caused by either exposure of the catalyst to excessive temperatures (thermal deactivation) or masking of the catalyst due to entrainment of particulate from the flue gas stream (fouling). Chemical

deactivation is caused by either an irreversible reaction of the catalyst with a contaminant in the gas stream (poisoning) or a reversible absorption of a contaminant on the surface of the catalyst (inhibition). Loss of catalyst activity through thermal degradation or poisoning is permanent, and reactivity can only be restored by replacing the catalyst.

In a North Dakota lignite application, SCR catalyst poisoning is expected to result from the presence of trace elements and strong alkaline substances in flue gas, including sodium (Na), potassium (K), and calcium (Ca). Alkaline metals can chemically attach to active catalyst pore sites and cause deactivation. Sodium and potassium are of prime concern especially in their water-soluble forms, which are more mobile and can penetrate into the catalyst pores. Earth metals, especially calcium, can react with SO₃ absorbed within the catalyst to form CaSO₄ and blind the catalyst.

North Dakota lignite contains relatively high levels of organically associated alkali and alkaline-earth elements, including Na, Ca, K, and Mg. Sodium levels in North Dakota lignite are typically 5 to 20 times higher than sodium levels in bituminous and subbituminous coals, and sodium compounds can represent between 5% and 11% of the ash generated from firing North Dakota lignite. These sodium levels, occurring in both the vapor phase and particulate phase, along with relatively high levels of potassium and calcium, significantly increase the potential for catalyst deactivation, plugging, and erosion. Based on the ash chemistry, a conventional high dust SCR arrangement would likely experience unacceptable catalyst deactivation rates.

As noted in section 3.1.1.2, during the first Regional Haze planning period, NDDH prepared a comprehensive technical feasibility assessment of high dust SCR on lignite-fired boilers (North Dakota Regional Haze SIP, Appendix B-5).³⁵ The NDDH concluded, based on the unique characteristics of North Dakota lignite-derived flue gas, that the high-dust SCR configuration was not a technically feasible or commercially available NO_x control option for North Dakota lignite-fired boilers such as AVS Units 1 and 2.³⁶ This determination was consistent with the NDDH's NO_x BACT determination for MRYS Units 1 & 2.³⁷ Reasons upon which NDDH based its

³⁵ See, North Dakota State Implementation Plan for Regional Haze, February 24, 2010, Appendix B.5, Best Available Retrofit Technology – Selective Catalytic Reduction Technical Feasibility Analysis for North Dakota Lignite, July 2009.

³⁶ *Id.* at pg. 19.

³⁷ As noted in section 3.1.1.2, contemporaneous with the Regional Haze SIP/FIP process, NDDH also prepared a BACT analysis for MRYS Units 1 & 2. In its BACT analysis, NDDH concluded that SCR was technically infeasible on a lignite-fired cyclone boiler, and selected SNCR as BACT. On December 21, 2011, the District Court issued a decision finding that the State's conclusion that SCR was not technically feasible was not unreasonable. See, U.S. v. Minnkota, 831 F. Supp. 2d at 1127-30

conclusion that high-dust SCR was not a technically feasible option for North Dakota lignite-fired boilers included, but were not limit to:³⁸

- 1) North Dakota lignite³⁹ has a higher organic matter content and contains a higher proportion of alkali metal constituents, especially sodium, than subbituminous coal. Approximately 75% of the total sodium in lignite is associated with the organic fraction of the lignite. During combustion, organic and water-soluble sodium vaporizes; consequently, combustion of the coal leads to higher flue-gas concentrations of alkali metals in vapor form.
- 2) The unburned or partially burned organic fraction of North Dakota lignite contains more sodium than other coals. Sodium can react with silicate particles causing a “stickiness” quality to the flue gas ash, resulting in increased ash deposition on heat transfer surfaces. Larger particles can fracture from heat-transfer surfaces (a.k.a. popcorn ash) and enter the flue gas stream. Consequently, deposition on surfaces of catalytic reactors occurs and rates of deposition are higher.
- 3) NO_x reduction occurs on the flat surfaces of a catalyst and in pores within the flat surfaces. The pores are open to the flue gas passing through the catalyst reactor. Condensed vapors, alkali sulfates and alkaline-earth oxides and silicates are minute particles (less than 1 microns), which enter pores of the catalyst (a.k.a. plugging) and prevent catalytic reaction with NO_x. Residual alkali vapors (Na, K, and Ca) displace hydrogen on fresh catalyst, which prevents catalytic reaction with NO_x (a.k.a poisoning) and reacts with sulfate to cause blinding of catalyst surfaces. Pore condensation of sodium also causes catalyst deactivation, which is a major deactivation mechanism. The rate of catalyst deactivation depends on the concentration and form of alkali in the flue gas; higher Na and K accelerate catalyst poisoning, blinding and plugging.
- 4) During the development of the initial planning period SIP, NDDH found that there were no SCR systems planned, constructed, or operating in the flue gas stream of boilers fired with North Dakota lignite. North Dakota lignite has certain coal characteristics that are uniquely different than Texas or Gulf Coast lignites, such as the larger proportion of organic matter and association of alkali, sodium specifically, with that organic matter.
- 5) Slipstream SCR reactors of the same design were installed at three power plants to test SCR for NO_x emissions control. One of the plants was cyclone fired with North Dakota lignite and the others with subbituminous coal. Deposition on the reactor surface after two months using the lignite was significantly greater; the deposits were rich in sodium, calcium, and sulfur. The tests confirmed catalyst blinding and plugging, but did not provide rates for catalyst deactivation. Tests also indicated that the deposits causing blinding and plugging of pores contained more sodium compared to Powder River Basin (PRB) coal.

Based on these findings, NDDH concluded that additional pilot scale testing would be required to assess issues specifically associated with the North Dakota lignite-generated flue gas characteristics, including potential impacts associated with:

³⁸ Findings and conclusions are summarized from the North Dakota Regional Haze SIP, Appendix B.5, pgs. 15-19.

³⁹ Although the BART determination specifically references Fort Union lignite, the findings would apply to all North Dakota lignites.

- the high level of soluble alkali in North Dakota lignite;
- the potential abrasive qualities of North Dakota lignite ash; and
- particle size and sticky nature of high alkaline North Dakota lignite ash.

The NDDH concluded that without pilot scale testing the long term NO_x reduction efficiency, the volume of the reactor, the catalyst pitch and life of catalyst, could not be predicted with a high degree of confidence. Noting that the BART Guidelines do not require source owners/operators to conduct extended trials to learn how to apply a technology on a totally new and dissimilar source type, and that technologies in the pilot scale testing stages of development are not considered as “available” for purposes of BART, NDDH determined that high dust SCR was not available, and thus, not technically feasible for units combusting North Dakota lignite.⁴⁰

Although the first planning period BART determinations, focused on North Dakota lignite-fired cyclone boilers (i.e., LOS Unit 2 and MRYS Units 1 & 2), technical issues regarding the high level of soluble alkali in North Dakota lignite, the particle size and sticky nature of high alkaline fly ash, and the potential abrasive qualities of North Dakota lignite ash would apply equally to wall-fired and tangentially fired boilers. Technical issues identified by NDDH during the first planning period would also apply to AVS Units 1 & 2; therefore, findings and conclusions from the first planning period BART determinations (Regional Haze SIP, Appendix B.5) and the MRYS Units 1 & 2 BACT analysis, are incorporated by reference into this reasonable progress four-factor analysis.

Based on a review of SCR installations on coal-fired boilers and a review of reported advances in SCR catalysts since the first planning period, deactivation rates due to soluble alkali compounds in the flue gas (including soluble sodium and potassium compounds) and the adhesive/cohesive characteristics and potential abrasive qualities of the North Dakota lignite-derived fly ash still remain a concern for North Dakota lignite-fired boilers. SCR has not been installed and successfully operated on a North Dakota lignite-fired boiler, and the bench scale and pilot-scale studies needed to better understand ash behavior and catalyst blinding/erosion with North Dakota lignite-derived fly ash, and to better understand catalyst deactivation mechanisms associated with high soluble alkali compound

⁴⁰ *Id.* at pg. 19. NDDH reached a similar conclusion in its BACT determination for NO_x control on MRYS Units 1 & 2, finding that high-dust SCR had not been deployed on the same or a similar source, and that the flue gas characteristics of North Dakota lignite are significantly different from other sources that have applied high-dust SCR. The NDDH found that these unique characteristics present significant challenges to the successful application of high-dust SCR for NO_x control, and that pilot testing would be needed to evaluate applicability of the control technology. Thus, NDDH concluded that because high-dust SCR is neither “available” nor “applicable” to the MRYS units, the control technology was technically infeasible and excluded from consideration as BACT. (See, Best Available Control Technology Determination for Control of Nitrogen Oxides for M.R. Young Station Units 1 and 2, April 2010).

concentrations in the flue gas have not been required or completed. Pilot-scale studies are needed to evaluate these issues to inform the development of advanced catalyst formulations, and to support the engineering and design studies needed to mitigate for potential deactivation routes (e.g., removing soluble alkali compounds from the flue gas and SCR design considerations such as catalyst formulation, catalyst pitch, reactor velocity, and catalyst surface and volume). Pilot-scale tests and engineering/design studies have not advanced since the first planning period's exhaustive analysis. These issues have not been resolved since the first planning period and still remain a significant barrier to the design and successful operation of high dust SCR on North Dakota lignite-fired boilers.

The BART Guidelines state that “[a] control technique is considered available...if it has reached the stage of licensing and commercial availability.”⁴¹ Commercial availability follows bench scale and laboratory testing and pilot scale testing. Consequently, the guidelines state that “you would not consider technologies in the pilot scale testing stages of development as ‘available’ for purposes of BART review.”⁴² Furthermore, source owners/operators are not expected to conduct extended trials to learn how to apply a technique on a dissimilar source type.⁴³ These BART guidelines also apply as a recommendation for the development of the LTS in the second planning period and the four factor analysis.⁴⁴ Because there are still unresolved issues associated with catalyst poisoning, catalyst blinding and plugging, and catalyst erosion; and engineering solutions have not yet been determined or demonstrated and the high dust configuration has not moved beyond pilot scale testing, high dust SCR is still not available, and thus, not a technically feasible NO_x control technology for AVS Units 1 and 2.

Low-Dust Configuration

In the low-dust configuration, the SCR reactor vessel is located in the flue gas stream after the particulate collection device (i.e. ESP or FF). Employing this configuration would represent a relatively low level of exposure to fly ash (with the exception of submicron ash particles), but a potentially high level of vapor-phase alkalis, such as sodium. This configuration can be used on units equipped with particulate control only or units equipped with particulate control followed by a WFGD control system. The existing dry FGD/FF control configuration at AVS Units 1 and 2 for SO₂ and particulate control would preclude the application of a low-dust SCR configuration since, by definition, the SCR would have to be located downstream of both the dry FGD and FF. At that location the SCR would be more appropriately defined as a tail-end SCR configuration, which is described in more detail in the following

⁴¹ 40 CFR Part 51 Appendix Y, Section D.2.1.

⁴² *Id.*

⁴³ *Id.*

⁴⁴ See, Draft EPA Guidelines, pg. 183.

section. Because AVS Units 1 and 2 are equipped with existing dry FGD/FF controls, low-dust SCR has no practical application on these units, and low-dust SCR is not considered a technically feasible NO_x control option for AVS Units 1 and 2.

Tail-End Configuration

In the tail-end configuration, the SCR reaction vessel is located in the flue gas stream after the particulate and FGD control systems. The potential advantage of a tail-end SCR configuration at AVS is that the flue gas will have passed through the dry FGD/FF system prior to the SCR catalyst. As such, there is the possibility that the mass transfer mechanism that results in the capture of SO₂ will also capture some of the vapor-phase sodium and the sodium-enriched submicron particles, reducing the risk of catalyst poisoning and/or deactivation.

Successful operation of the tail-end configuration would also require a capital and operating cost-intensive gas-to-gas heat exchanger to reheat the flue gas from approximately 170 °F downstream of the existing FF to approximately 550°F to support the SCR NO_x reactions. After the flue gas passes through the SCR (at approximately 550°F), it would pass through the hot side of the gas-to-gas heat exchanger to cool the flue gas to 150°F prior to the exhaust stack. Although this stack gas temperature would be lower than the current stack temperature (165-170°F), it is still higher than the adiabatic saturation temperature of the flue gas (i.e., approximately 135°F). As such, it is likely that the existing stack could be reused with minor modifications.

During the first planning period, NDDH initially concluded, based on preliminary information provided by SCR catalyst vendors, that the tail-end SCR configuration would be a technically feasible option for units firing North Dakota lignite.⁴⁵ However, as part of the MRYS NO_x BACT determination process, detailed information describing the expected ash characteristics and flue gas characteristics was provided to two SCR catalyst vendors (CERAM Environmental, Inc. (CERAM) and Haldor Topsoe, Inc.). Based on their review of the data, both vendors concluded that they would not be able to provide a catalyst life guarantee for either low-dust or tail-end SCR without pilot-scale testing.⁴⁶

During the BACT review process, both companies made statements bringing into question the technical feasibility of either low-dust or tail-end SCR. For example, CERAM stated that the high levels of sodium oxide (Na₂O) in the ash for North Dakota lignite are not commonly found in subbituminous and bituminous coals which are fired in

⁴⁵ See, North Dakota Regional Haze SIP, Appendix B.5, pg. 25.

⁴⁶ See, *United States v. Minnkota*, 831 F. Supp. 2d, at 1117.

boilers equipped with SCR systems, and that it was unaware of any SCR application experience in the industry with the level and form of sodium in the North Dakota lignite-derived ash. CERAM stated further that small aerosol particles can penetrate and neutralize active catalyst sites even in dry conditions, and that catalyst installed even in low dust and tail-end locations can be poisoned from exposure to the high levels of phosphorous, sodium, and potassium found in the mineral analyses provided for the MRYS BACT analysis.⁴⁷ Similarly, Haldor Topsoe stated that the potential exists that physical deactivation due to catalyst blinding and plugging could be severe enough to make SCR a non-viable option for controlling NO_x emissions.

Based on information provided by SCR design engineering firms and SCR catalyst vendors, NDDH made the following findings and conclusions with respect to the technical feasibility of low-dust and tail-end SCR on a North Dakota lignite-fired boiler:⁴⁸

- 1) There has never been a full scale SCR of any type installed on a facility that burns North Dakota lignite.
- 2) To determine technical feasibility of tail-end SCR, one must compare the flue gas characteristics generated from firing North Dakota lignite to the flue gas characteristics of other source types to which these control technologies have been applied previously.
- 3) Flue gas characteristics of boilers firing North Dakota lignite are significantly different from other boilers where SCR has been applied.
- 4) North Dakota lignite contains high quantities of soluble sodium and potassium which can cause catalyst reaction site poisoning, blinding, and plugging of catalyst pores and channels, and that the soluble sodium and potassium can also form sulfates that can blind and plug the catalyst pores and plug the catalyst channels.
- 5) Both CERAM and Haldor Topsoe indicated that they would not provide a guarantee for the catalyst life without successful pilot scale testing being done.

Technologies in the pilot scale testing phase of development need not be considered as available control technologies. Based on the fact that SCR had not been installed nor effectively operated on an North Dakota lignite-fired unit, the lack of a commercially viable vendor guarantee, and the need to conduct pilot-scale testing to evaluate potentially significant operational and design issues, NDDH concluded that the use of SCR technology, including low-dust and tail-end SCR, on the lignite-fired MRYS boilers would be technically infeasible.⁴⁹

⁴⁷ *Id.*

⁴⁸ Findings and conclusions are summarized from United States v. Minnkota, pgs 1115-1116.

⁴⁹ Best Available Control Technology Determination for Control of Nitrogen Oxides for M.R. Young Station Units 1 and 2, April, 2010, pg. 21.

Although the MRYS BACT determination, and the initial planning period BART determinations, focused on North Dakota lignite-fired cyclone boilers (i.e., LOS Unit 2 and MRYS Units 1 & 2), technical issues regarding the high level of soluble alkali in North Dakota lignite-derived flue gas would also apply to AVS Units 1 & 2. Therefore, findings and conclusions included in the MRYS Units 1 & 2 BACT analysis and the initial planning period BART determinations (Regional Haze SIP, Appendix B.5) are incorporated by reference into this four-factor analysis.

Based on a current review of SCR installations on coal-fired boilers, and a review of reported advances in SCR catalysts since the first planning period, deactivation rates due to soluble alkali compounds in the flue gas (including soluble sodium and potassium compounds) still remain a concern for North Dakota lignite-fired boilers. Tail-end SCR has not been demonstrated on a North Dakota lignite-fired boiler, and there are still significant technical concerns associated with the availability of existing SCR catalysts on a lignite-fired unit. Catalyst in a tail-end SCR will still be vulnerable to alkali poisoning, pore pluggage, and premature catalyst deactivation, and it is not known whether the comparatively high levels of soluble sodium and potassium in North Dakota lignite will be effectively removed by the upstream dry FGD/FF. Furthermore, the potential exists for fine particulate remaining in the flue gas to get into the catalyst pores reducing catalyst activity. Pilot-scale studies are needed to better understand catalyst deactivation mechanisms associated with high soluble alkali compound concentrations in the flue gas have not been completed.

In order to understand the effect of North Dakota lignite-derived flue gas on tail-end SCR catalyst, identify potential design solutions, and evaluate the technical feasibility and effectiveness of tail-end SCR at AVS Units 1 and 2 with any degree of certainty, pilot scale testing of the control configuration would be needed. Because there are still unresolved issues associated with catalyst poisoning, it's very unlikely that Basin Electric could obtain a viable commercial offering for tail-end SCR on AVS Units 1 and 2 without extended pilot-scale tests.

During the first planning period NDDH determined that tail-end SCR was not available, and thus, not a technically feasible NO_x control option for North Dakota lignite-fired boilers. Although the NDDH's control technology evaluation during the first planning period specifically focused on North Dakota lignite-fired cyclone boilers, technical issues regarding catalyst deactivation mechanisms associated with the high level of soluble alkali in North Dakota lignite would apply equally to wall-fired and tangentially-fired boilers. The administrative record developed during the first planning period, including the BART determinations and MRYS BACT analysis, supports the conclusion that tail-end SCR is not an available NO_x control option for AVS Units 1 & 2. An evaluation of SCR installations and reported advances in SCR catalysts since the first planning period, coupled with

the fact that tail-end SCR has not been demonstrated on a North Dakota lignite-fired boiler, and the likelihood that Basin Electric could not obtain a viable commercial offering for tail-end SCR without extended pilot-scale testing, continues to support the conclusion that tail-end SCR is not an available NO_x control technology. Nevertheless, because the first planning period BART analysis (and the MRYs BACT analysis) focused on cyclone boilers, Basin Electric has elected to include tail-end SCR as a potentially feasible control option and carry it forward to the cost impact evaluation (Section 5.2.2.1). Based on controlled NO_x emissions achieved in practice at existing bituminous- and subbituminous-fired units, S&L assumed that the tail-end SCR control option could achieve an average controlled NO_x emission rate of 0.05 lb/MMBtu.

5.2.2.2 Selective Non-Catalytic Reduction

Selective non-catalytic reduction (SNCR) involves the direct injection of ammonia or urea (CO(NH₂)₂) at high flue gas temperatures (approximately 1,600°F – 2,100°F) in an oxidizing environment. The ammonia or urea reacts with NO_x in the flue gas to produce N₂ and water as shown below.

Flue gas temperature at the point of reagent injection can greatly affect NO_x removal efficiencies and the quantity of NH₃ or urea that will pass through the SNCR unreacted (referred to as NH₃ slip). In general, SNCR reactions are effective in the range of 1,600°F – 2,100°F. At temperatures below the desired operating range, the NO_x reduction reactions diminish and unreacted NH₃ emissions increase. Above the desired temperature range, NH₃ is oxidized to NO_x resulting in low NO_x reduction efficiencies.

Mixing of the reactant and flue gas within the reaction zone is an important factor to SNCR performance. In large boilers, the physical distance over which reagent must be dispersed increases, and the surface area/volume ratio of the convective pass decreases. Furnace geometry, urea spray coverage, and droplet size must be considered when developing good mixing of reagent and flue gas, delivery of reagent in the proper temperature window, and sufficient residence time of the reagent and flue gas in that temperature window. As the boiler cycles in load, the optimum injection region may change. Thus most facilities require multiple injection zones which are placed in and out of service as the unit ramps in load. This can include modifying the zones of injectors that are operating and different loads and temperatures.

Retractable multinozzle lances (MNLs) are sometimes used to improve SNCR performance, especially if the furnace exit flue gas temperatures are too high. The retractable lances allow injection into the appropriate temperature zone more so than wall injectors, depending on the unit load and temperatures. The MNLs also help improve performance by refining the spray pattern for quicker vaporization of the conveying water. MNLs are often used in conjunction with wall injection to provide optimized coverage while reducing reagent cost.

In addition to temperature and mixing, several other factors influence the performance of an SNCR system, including residence time, reagent-to-NO_x ratio, and fuel sulfur content. Increasing the normalized stoichiometric ratio can improve NO_x removal. This is completed by increasing urea solution flow through the injectors or changing the concentration of urea in the solution. However, too high of reagent injection rates will increase the ammonia slip beyond the recommended 10 ppmvd limit. Above this concentration, there are expected to be major impacts to the formation of ammonia salts on the boiler tube banks, reducing heat transfer efficiency, and air heater baskets, causing corrosion.

SNCR can be applied on pulverized coal boiler due to having reasonable temperature windows and residence time, however the potential NO_x reduction is boiler-specific. SNCR has been used as a retrofit NO_x control system on pulverized coal, fluidized bed boilers, and cyclone boilers. Furthermore, SNCR can be implemented on boilers equipped with LNB, overfire air, or SOFA systems. Based on the boiler residence time, temperature profile, and stoichiometry, as well as input from SNCR OEMs, it is estimated that an SNCR system could achieve an average controlled NO_x emission rate of approximately 0.09 lb/MMBtu (approximately 10% below the baseline emission rate of 0.10 lb/MMBtu) while limiting ammonia slip to 10 ppmvd. It should be noted that computational fluid dynamic modeling and temperature mapping of the boiler would be needed to confirm that the incremental reduction in NO_x emission is achievable without creating unacceptable operational issues.

5.2.2.3 Rich Reagent Injection

Similar to SNCR, the concept of rich reagent injection (RRI) is to use a nitrogen-containing additive (urea) injected into a reducing environment to promote peak NO_x reduction efficiency. RRI is a commercial technology for cyclone boilers only. Since the AVS units are pulverized coal boilers, this technology is not considered a technically feasible NO_x control technology at AVS.

5.2.2.4 Gas Reburn

Gas reburn is a retrofit technique that has been used to control NO_x emissions from coal- and oil-fired boilers. Gas reburn involves combustion in three distinct zones within the boiler: (1) a primary combustion zone, where the primary fuel is fired using conventional burners; (2) a reburn zone, where secondary fuel, typically natural gas, is introduced into the boiler; and (3) an OFA burnout zone.

In the primary zone of coal-fired boilers, coal is fired through LNCFS, at a rate corresponding to approximately 80% to 90% of the total heat input. Natural gas reburn fuel is then injected above the primary combustion zone under fuel-rich conditions at a rate corresponding to approximately 10% to 20% of the total heat input (on a Btu/hour basis). The fuel-rich reburn zone creates a reducing (sub-stoichiometric) region within the boiler where the natural gas, principally methane (CH_4), breaks down to produce hydrocarbon radicals (CH and CH_2). The hydrocarbon radicals react with NO_x produced in the primary combustion zone to form nitrogen (N_2) and water vapor. Because the natural gas is not completely combusted in the reburn zone, gases exiting the reburn zone will contain considerable CO and unburned hydrocarbons; therefore, additional OFA is introduced above the reburn zone to complete the combustion process.

Critical design parameters that affect the feasibility and performance of a gas reburn retrofit system include: (1) baseline NO_x concentration; (2) reburn zone temperature, residence time, and stoichiometry; (3) OFA burnout zone temperature and residence time; and (4) mixing of the reburn fuel and overfire air with the bulk flue gas.

Gas reburn can have a positive impact on emissions of NO_x ; however, in order to make a meaningful prediction of the NO_x removal capabilities at AVS, extensive testing at each unit would be required because the performance is significantly dependent upon boiler operating characteristics. As such, gas reburn is not considered a technically feasible NO_x control technology at AVS.

5.2.2.5 Innovative Technologies

NO_x StarTM

The NO_x StarTM process, also known as selective autocatalytic reduction (SACR), uses a continuous controlled amount of ammonia-based reagent with relatively small amounts of hydrocarbon to reduce NO_x emissions. The hydrocarbon is introduced into the flue gas at the convective pass of the boiler, with elevated temperatures. At the elevated temperatures, the hydrocarbon auto-ignites to form a plasma of free radicals that auto catalyzes the reaction of NH_3 and NO_x to form N_2 and H_2O . The hydrocarbon and ammonia are added through banks of nozzles

in the superheat or reheat sections of the boiler. The injection location is determined by the location of the temperature windows for the "plasma creation zone" as well as the reaction zone for the ammonia.

To date, only one full-scale demonstration has been conducted to evaluate the technology on utility-sized boilers similar to AVS. The process is an emerging NO_x control, and there is limited information available to evaluate its technical feasibility and long-term effectiveness on a large lignite-fired boiler. Potential NO_x removal efficiencies would be a function of NH₃-NO_x mixing, flue gas temperature, flue gas composition, and residence time downstream of the injection lances.

Because this is an emerging technology, long-term full-scale demonstration testing is required to demonstrate its effectiveness at AVS. It is likely that extensive design engineering and testing would be required to evaluate the technical feasibility and long-term effectiveness of the control system. Detailed design of the lances, mixing, optimization of the reagent supply across the boiler convective pass, flue gas temperatures, and flow distribution would have to be studied. Interference with the tube pendants in the convective pass may also make this more difficult to install. Installing a hydrocarbon distribution grid may present a problem with large boilers because of the span needed to uniformly distribute the reagent, interference with the tube pendants in the convective pass, and an additional booster fan may be needed. As such, NO_xStar™ is not considered a technically feasible NO_x control technology at AVS.

PerNO_xide

PerNO_xide utilizes hydrogen peroxide (H₂O₂) to reduce NO_x emissions. Hydrogen peroxide is injected into the ducts ahead of the air preheater and oxidizes the NO to NO₂, which is then captured in a downstream FGD system. To date, the technology has only been tested on a pilot-scale, and it has not been demonstrated on any coal-fired boilers. It is likely that extensive design engineering and testing would be required to evaluate the scale-up potential and long-term effectiveness of the system on AVS. As such, PerNO_xide is not considered a technically feasible NO_x control technology at AVS.

LoTOX®

The LoTO_x system is a gas-phase, low-temperature oxidation system, wherein ozone is injected into the flue gas stream to oxidize NO and NO₂ to N₂O₅ before being removed in a wet scrubber. This highly oxidized species of NO_x is water-soluble and rapidly reacts with water to form nitric acid. The conversion of NO_x to nitric acid occurs as the N₂O₅ contacts liquid sprays in the scrubber. The nitric acid would react with the alkali compounds in

the scrubber and would be eliminated via the scrubber waste and byproduct streams. The LoTO_x system requires on demand ozone generation from a liquid oxygen supply.

The LoTO_x system has been successfully applied in refinery applications however; there are no full-scale installations on coal-fired boilers. According to vendors, one coal-fired boiler demonstration on a 25-MW boiler was performed which showed 90% NO_x removal. It is likely that extensive design engineering and testing would be required to evaluate the scale-up potential and long-term effectiveness of the system at AVS. As such, LoTO_x is not considered a technically feasible NO_x control technology at AVS.

Water Injection

The principle behind this technology is to inject an atomized water spray into the high-NO_x production zones of a cyclone burner or in the core of the flame for other furnaces. The water spray reduces the temperature and results in lower NO_x production within this zone. Developers claim that water injection through burners used in tangential-fired and wall-fired units will also lower the flame temperature and, hence, lower NO_x production. However, only laboratory results are available to demonstrate this technology's effectiveness in coal-fired applications.

Water injection is well demonstrated for combustion turbine applications for NO_x reduction. However, there is insufficient experience and demonstration data in coal-fired applications. As such, water injection is not considered a technically feasible NO_x control technology at AVS.

5.2.2.6 Technical Feasibility Summary

Table 5-5 summarizes the results of the feasibility evaluation of available NO_x control options for AVS Units 1 and 2.

Table 5-5. Technically Feasible NO_x Control Options

NO _x Control Option	Technically Feasible (Yes/No)	Control Percentage (Note 1)	Technical Feasibility Summary
Selective Non-Catalytic Reduction (SNCR)	Yes	10%	SNCR is considered an available and technically feasible NO _x control technology for AVS Units 1 and 2. Computational fluid dynamic modeling and temperature mapping of the boiler would be needed to confirm that the incremental reduction in NO _x emissions is achievable without creating unacceptable operational issues.
Rich Reagent Injection	No	0%	RRI is not considered an available or technically feasible NO _x control option at AVS.
Gas Reburn	No	0%	Gas reburn is not considered an available or technically feasible NO _x control technology at AVS Units 1 and 2.
Innovative Technologies: NO _x Star™ PerNO _x ide LoTO _x Water Injection	No	0%	Innovative NO _x control technologies are evaluated in Section 5.2.2.5. In all cases, the technologies have not been demonstrated on a large North Dakota lignite-fired boiler. Extensive testing and design engineering would be required to evaluate the technical feasibility and long-term effectiveness of each innovative control system on AVS Units 1 and 2. Therefore, the innovative NO _x control technologies are not considered available control options and are not technically feasible NO _x control options for AVS Units 1 and 2.
Selective Catalytic Reduction:			
High-dust configuration	No	0%	Due to significant unresolved issues associated with catalyst poisoning, catalyst blinding and plugging, and catalyst erosion; and based on the finding that engineering solutions have not been determined or demonstrated and the high dust configuration has not moved beyond pilot scale testing, high dust SCR is not an available or technically feasible NO _x control technology for AVS Units 1 and 2.
Low-dust configuration	No	0%	Because AVS Units 1 and 2 is equipped with existing dry FGD/FF control systems, low-dust SCR has no practical application on the unit, and low-dust SCR is not considered an available or technically feasible NO _x control option for AVS Units 1 and 2.

NO _x Control Option	Technically Feasible (Yes/No)	Control Percentage (Note 1)	Technical Feasibility Summary
Tail-end configuration	Yes	50%	Tail-end SCR has not been installed on a North Dakota lignite-fired unit, and extended trials would be needed to better understand the design and operation of tail-end SCR on AVS Units 1 and 2. Because there are unresolved issues associated with catalyst poisoning, it's unlikely that Basin Electric could obtain a viable commercial offering for tail-end SCR on AVS Units 1 and 2. Nevertheless, during the initial planning period, NDDH concluded that tail-end SCR was a technically feasible NO _x control technology for a North Dakota lignite-fired boiler, and evaluated the costs and cost-effectiveness of the control system. Based on the approach NDDH used during the initial planning period (i.e., assuming technical feasibility and evaluating the control system for costs and cost-effectiveness), tail-end SCR will be carried forward to the four factor analysis.

Note 1. Control percentage calculated using the baseline NO_x emission rate and the achievable NO_x emission rate for each technically feasible control option.

5.2.3 Evaluate Technically Feasible NO_x Control Options for Effectiveness

The technically feasible NO_x control technologies for Units 1 and 2 are listed in Table 5-6 and Table 5-7 in descending order of control efficiency. Table 5-6 and Table 5-7 also provide control option-specific NO_x emission rates in terms of lb/MMBtu. Emission rates shown represent average emission rates that the control options would be expected to achieve during normal operations.

**Table 5-6. Evaluate Technically Feasible NO_x Control Options by Effectiveness for AVS Unit 1
 (Baseline Average Emissions)**

Alt. No.	Control Technology	NO _x Emission Rate ^(Note 1) lb/MMBtu	% Reduction from Baseline ^(Note 2)	NO _x Emission Rate ^(Note 1) lb/hr	NO _x Emission Rate ^(Note 1) tons/yr
B	SCR – tail-end configuration ^(Note 2)	0.05	52%	206	870
A	SNCR	0.09	10%	388	1,636
--	Baseline (existing OFA/LNCFS)	0.10		427	1,802
--	Permit Limit (assume 50/50 split for each unit)	0.17 (30-day) 0.50 (3-hour)	--	2,465 lb/hr (3-hr average)	

Note 1. Emission rates shown represent average emission rates that the control options would be expected to achieve on an on-going long-term basis under normal operating conditions for AVS Unit 1. Emission rates are provided for comparative purposes, and should not be construed to represent proposed emission limits. Corresponding permit limits must be evaluated on a control system-specific basis.

Note 2. Tail-end SCR has not been installed on a North Dakota lignite-fired unit, and extended trials would be needed to better understand the design and operation of tail-end SCR on AVS Unit 1. Nevertheless, during the initial planning period, NDDH concluded that tail-end SCR was a technically feasible NO_x control technology for a North Dakota lignite-fired boiler, and evaluated the costs and cost-effectiveness of the control system. For consistency with NDDH's conclusion from the first planning period, tail-end SCR will be carried forward to the four factor analysis.

**Table 5-7. Evaluate Technically Feasible NO_x Control Options by Effectiveness for AVS Unit 2
 (Baseline Average Emissions)**

Alt. No.	Control Technology	NO _x Emission Rate ^(Note 1) lb/MMBtu	% Reduction from Baseline	NO _x Emission Rate ^(Note 1) lb/hr	NO _x Emission Rate ^(Note 1) tons/yr
B	SCR – tail-end configuration ^(Note 2)	0.05	52%	224	916
A	SNCR	0.09	10%	421	1,722
--	Baseline (existing OFA/LNCFS)	0.10		466	1,904
--	Permit Limit (assume 50/50 split for each unit)	0.17 (30-day) 0.50 (3-hour)	--	2,465 lb/hr (3-hr average)	

Note 1. Emission rates shown represent average emission rates that the control options would be expected to achieve on an on-going long-term basis under normal operating conditions for AVS Unit 2. Emission rates are provided for comparative purposes, and should not be construed to represent proposed emission limits. Corresponding permit limits must be evaluated on a control system-specific basis.

Note 2. Tail-end SCR has not been installed on a North Dakota lignite-fired unit, and extended trials would be needed to better understand the design and operation of tail-end SCR on AVS Unit 2. Nevertheless, during the initial planning period, NDDH concluded that tail-end SCR was a technically feasible NO_x control technology for a North Dakota lignite-fired boiler, and evaluated the costs and cost-effectiveness of the control system. For consistency with NDDH's conclusion from the first planning period, tail-end SCR will be carried forward to the four factor analysis.

Table 5-8 provides control option-specific NO_x emission rates in terms of lb/MMBtu based on the projected future maximum emission rates. Emission rates shown represent the projected future maximum emission rates that the control options would be expected to achieve during normal operations.

Table 5-8. Evaluate Technically Feasible NO_x Control Options by Effectiveness – AVS Unit 1 or 2 (Projected Future Maximum Emissions)

Alt. No.	Control Technology	NO _x Emission Rate ^(Note 1) lb/MMBtu	% Reduction from Baseline	NO _x Emission Rate ^(Note 1) lb/hr	NO _x Emission Rate ^(Note 1) tons/yr
B	SCR – tail-end configuration ^(Note 2)	0.05	52%	247	1,080
A	SNCR	0.09	10%	463	2,030
--	Baseline Unit 1 (existing OFA/LNCFS)	0.10	--	510	2,235
--	Baseline Unit 2 (existing OFA/LNCFS)	0.10	--	512	2,244
--	Permit Limit (assume 50/50 split for each unit)	0.17 (30-day) 0.50 (3-hour)	--	2,465 lb/hr (3-hr average)	

Note 1. Emission rates shown represent projected future maximum emission rates that the control options would be expected to achieve on an on-going long-term basis under 100% capacity factor operation for AVS Unit 1 or 2. Emission rates are provided for comparative purposes, and should not be construed to represent proposed emission limits. Corresponding permit limits must be evaluated on a control system-specific basis.

Note 2. Tail-end SCR has not been installed on a North Dakota lignite-fired unit, and extended trials would be needed to better understand the design and operation of tail-end SCR on AVS Units 1 and 2. Nevertheless, during the initial planning period, NDDH concluded that tail-end SCR was a technically feasible NO_x control technology for a North Dakota lignite-fired boiler, and evaluated the costs and cost-effectiveness of the control system. For consistency with NDDH's conclusion from the first planning period, tail-end SCR will be carried forward to the four factor analysis.

5.3 NO_x COST OF COMPLIANCE (STATUTORY FACTOR ONE)

The economic analysis performed as part of the four factor analysis examines the cost-effectiveness of each technically feasible control technology, on a dollar per ton of pollutant removed basis. Annual emissions, calculated for a particular control device, are subtracted from baseline annual emissions to calculate tons of pollutant controlled per year. For units with existing controls, the base case represents existing baseline actual emissions. Annual costs for each control option are calculated relative to the base case by adding annual O&M costs to the annualized cost of capital and, if applicable, lost revenue due to extended outage required for installation of control equipment. Capital costs and lost revenues were annualized using a capital recovery factor

based on an annual interest rate of 5.25% and equipment life of 20 years.⁵⁰ Cost effectiveness (\$/ton) of a particular control option is simply the annual cost (\$/yr) divided by the annual reduction in annual emissions (ton/yr). In addition to cost-effectiveness relative to the base case, the incremental cost-effectiveness to go from one level of control to the next, more stringent, level of control may also be calculated to evaluate the incremental cost effectiveness of the more stringent control.

Capital and O&M cost estimates were developed for each of the technically feasible NO_x control options. The AVS Units 1 and 2 cost estimates are conceptual in nature; thus, S&L did not procure equipment quotes specifically for the Units 1 and 2 control system upgrades. Rather, equipment costs are based on conceptual designs developed for the retrofit control systems, preliminary equipment sizing developed for the major pieces of equipment (based on AVS-specific design parameters, including typical fuel characteristics, full load heat input, and flue gas temperatures and flow rates), and recent pricing for similar equipment. S&L would characterize the cost estimates for the AVS Units 1 and 2 retrofit technologies as “concept screening” cost estimates generally based on parametric models, judgment, or analogy.

Control technology equipment costs for the retrofit options were developed by scaling cost estimates prepared by S&L for other similar projects. Major equipment costs were developed based on equipment costs recently developed for similar projects, and include the equipment, material, labor, and all other direct costs needed to retrofit the units with the control technology. Sub-accounts for the capital cost estimates (e.g., mobilization and demobilization, consumables, Contractor G&A expense, freight on materials, etc.) were developed by applying ratios from detailed cost estimates that were prepared for projects with similar scopes.

Fixed O&M costs include operating labor, maintenance labor, maintenance material, and administrative labor. Variable O&M costs include the cost of consumables, including reagent, water consumption, and auxiliary power requirements. Auxiliary power requirements reflect the additional power requirements associated with the operation of the new control technology (compared to the existing technology). All O&M costs reflect the incremental increase in O&M costs compared to the costs incurred to operate the existing control systems.

⁵⁰ The assumed 20-year equipment life is consistent with the control system equipment life used by NDDH in its evaluation of NO_x and SO₂ control technologies for BART-eligible sources. (see, e.g., ND Regional Haze Final SIP, Appendix C.1, “BART Determination Study for Leland Olds Station Units 1 & 2, Basin Electric Power Cooperative, August 2006, pgs. 64 (NO_x controls) and 158 (SO₂ controls). See also, ND Regional Haze Final SIP, Appendix C4, “NO_x Best Available Control Technology Study for Milton R. Young Station Unit 1, Minnkota Power Cooperative, Inc., October 2006, pg. 3-22).

In addition to the cost effectiveness relative to the base case, the incremental cost-effectiveness to go from one level of control to the next more stringent level of control will also be calculated to evaluate the cost effectiveness of the more stringent control.

5.3.1 NO_x Average Annual Economic Evaluation

Table 5-9 presents the capital costs and annual operating costs associated with building and operating each control system. Table 5-9 shows the average annual and incremental cost effectiveness for each control system. Additional cost details are provided in Appendix D.

Table 5-9. NO_x Control Cost Summary (Average Annual)

AVS Unit No.	Alt. No.	NO _x Control Option	Total Capital Investment \$	Annual Capital Recovery Cost \$/yr	Annual Operating Cost \$/yr	Total Annual Cost \$/yr
Unit 1	B	SCR – tail-end configuration	\$221,396,000	\$18,144,000	\$18,201,000	\$36,345,000
	A	SNCR	\$16,356,000	\$1,340,000	\$1,945,000	\$3,285,000
Unit 2	B	SCR – tail-end configuration	\$221,396,000	\$18,144,000	\$18,207,000	\$36,351,000
	A	SNCR	\$16,356,000	\$1,340,000	\$1,970,000	\$3,310,000

Table 5-10. NO_x Emissions Control System Cost Effectiveness (Average Annual)

AVS Unit No.	Alt. No.	NO _x Control Option	Total Annual Cost \$	Expected Emission Reduction (Note 2) tons NO _x /yr	Average Annual Cost- Effectiveness (Note 2) \$/ton NO _x removed	Incremental Annual Cost- Effectiveness (Note 1) \$/ton NO _x removed
Unit 1	B	SCR – tail-end configuration	\$36,345,000	931	\$39,035	\$43,161
	A	SNCR	\$3,285,000	165	\$19,893	
Unit 2	B	SCR – tail-end configuration	\$36,351,000	988	\$36,792	\$40,997
	A	SNCR	\$3,310,000	182	\$18,179	

Note 1. Incremental cost-effectiveness represents the incremental increase in annual costs (\$/yr) divided by the incremental increase in annual NO_x emissions reductions (tpy) between a control option and the next most effective option. For the option “SCR,” incremental cost compares to the option “SNCR.”

Note 2. Expected emission reductions and average annual cost-effectiveness based on baseline NO_x emission rate and capacity factor during baseline NO_x period for each AVS Unit.

Table 5-10 indicates that the average annual cost effectiveness of the technically feasible NO_x control options for Unit 1 range from \$19,893 per ton (SNCR) to \$39,035 per ton (SCR – Tail end configuration) NO_x removed; and for Unit 2 ranges from \$18,179 per ton to \$36,792 per ton NO_x removed.

Installation of an SNCR system is expected to achieve approximately 10% NO_x reduction. The cost effectiveness of this option is approximately \$19,000 per ton.

Tail-end SCR system costs have been included to remain consistent with the approach used by NDDH during the initial planning period. Based on preliminary cost estimates, the cost effectiveness of a tail-end SCR system is approximately \$39,000 per ton. Compared to the SNCR control option, the incremental cost effectiveness is approximately \$43,000 per ton.

5.3.2 NO_x Projected Future Maximum Economic Evaluation

Table 5-11 presents the capital costs and annual operating costs associated with building and operating each control system; annual operating costs are based on the units operating at 100% capacity factor. Table 5-12 shows the average annual and incremental cost effectiveness for each control system with emissions reductions and cost effectiveness values based on 100% capacity factors and projected future maximum emission rates. Additional cost details are provided in Appendix D.

Table 5-11. NO_x Control Cost Summary (Projected Future Maximum)

AVS Unit No.	Alt. No.	NO _x Control Option	Total Capital Investment \$	Annual Capital Recovery Cost \$/yr	Annual Operating Cost \$/yr	Total Annual Cost \$/yr
Unit 1	B	SCR – tail-end configuration	\$221,396,000	\$18,144,000	\$18,788,000	\$36,932,000
	A	SNCR	\$16,356,000	\$1,340,000	\$2,074,000	\$3,414,000
Unit 2	B	SCR – tail-end configuration	\$221,396,000	\$18,144,000	\$18,649,000	\$36,793,000
	A	SNCR	\$16,356,000	\$1,340,000	\$2,075,000	\$3,415,000

Note 1. Annual operating costs based on baseline NO_x emissions and 100% capacity factor for each AVS

Table 5-12. NO_x Emissions Control System Cost Effectiveness (Based on Projected Future Maximum Emissions)

AVS Unit No.	Alt. No.	NO _x Control Option	Total Annual Cost \$	Expected Emission Reduction tons NO _x /yr	Average Annual Cost-Effectiveness \$/ton NO _x removed	Incremental Annual Cost-Effectiveness (Note 1) \$/ton NO _x removed
Unit 1	B	SCR – tail-end configuration	\$36,932,000	1,155	\$31,977	\$35,278
	A	SNCR	\$3,414,000	205	\$16,667	
Unit 2	B	SCR – tail-end configuration	\$36,793,000	1,165	\$31,589	\$35,131
	A	SNCR	\$3,415,000	215	\$15,910	

Note 1. Incremental cost-effectiveness represents the incremental increase in annual costs (\$/yr) divided by the incremental increase in annual NO_x emissions reductions (tpy) between a control option and the next most effective option. For the option “SCR,” incremental cost compares to the option “SNCR.”

Note 2. Expected emission reductions and average annual cost-effectiveness based on baseline NO_x emissions and 100% capacity factor for each AVS Unit.

Table 5-12 indicates that the average annual cost effectiveness based on projected future maximum of the technically feasible NO_x control options for Unit 1 from \$16,667 per ton (SNCR) to \$31,977 per ton (SCR – Tail end configuration) NO_x removed; and for Unit 2 ranges from \$15,910 per ton to \$31,589 per ton NO_x removed.

Installation of an SNCR system is expected to achieve approximately 10% NO_x reduction from the projected future maximum emissions. The cost effectiveness of this option is approximately \$16,000 per ton.

Tail-end SCR system costs have been included to remain consistent with the approach used by NDDH during the initial planning period. Based on preliminary cost estimates, the cost effectiveness of a tail-end SCR system is approximately \$31,000 per ton. Compared to the SNCR control option, the incremental cost effectiveness is approximately \$35,000 per ton.

6. TIME NECESSARY FOR COMPLIANCE (STATUTORY FACTOR TWO)

The time necessary for compliance is generally defined as the time needed for full implementation of the technically feasible control options. This includes the time needed to develop and implement the regulations, as well as the time needed to install the selected control equipment. The time needed to install the control equipment includes time for equipment procurement, design, fabrication, and installation. Therefore, compliance deadlines must consider the time necessary for compliance by setting a compliance deadline that provides a reasonable amount of time for the source to implement the control measure.

Table 6-1 and Table 6-2 include estimated timeframes needed to implement each of the technically feasible control. The estimated timeframes do not account for time needed for North Dakota to develop and implement the regulations; therefore, the scheduled activities identified below commence immediately after SIP approval and are subject to the maintenance outage schedules of the individual unit.

Table 6-1. SO₂ Emissions Control System Implementation Schedule

SO ₂ Control Option	Alt. No.	Design / Specification / Procurement (months)	Detail Design / Fabrication (months)	Construction / Commissioning / Startup / Tuning (months)	Compliance Date (months after SIP approval)
FGD operational improvements – Station Work Practice (Note 1)	A	0	0	3	3
FGD operational improvements – Increase Ca:S Stoichiometric Ratio	B	12	15	24 ^(Note 2)	No later than 60 months
Dry FGD (CDS) + Existing FF	D	12	20	24	No later than 60 months
Wet FGD	E	12	22	26	No later than 60 months

Note 1. Although this option would not require design/fabrication and construction months, Basin Electric would need 2-3 months to update O&M manuals and personnel training for the change to the work practice of the existing DFGD systems.

Note 2. Requires coordination with normal tri-annual outage schedules.

SNCR	A	10	6	6	No later than 60 months
SCR – Tail-End Configuration	B	10	18	24	No later than 60 months

7. ENERGY AND NON-AIR QUALITY ENVIRONMENTAL IMPACTS (STATUTORY FACTOR THREE)

The primary purpose of the environmental impact analysis is to assess collateral environmental impacts due to control of the regulated pollutant in question. Environmental impacts may include solid or hazardous waste generation, discharges of polluted water from a control device, visibility impacts, increased emissions of other criteria or non-criteria pollutants, increased water consumption, and land use impacts from waste disposal.

7.1 ENVIRONMENTAL IMPACTS

AVS Units 1 and 2 are currently equipped with LNCFS/OFA for NO_x control and dry scrubber technology for SO₂ control. The hydrated lime reactant used in a dry scrubbing system reacts with SO₂ in the flue gas to form calcium sulfate and calcium sulfite solids. The solids are captured in the existing FF particulate control system and either returned to the system for reuse or removed from the system as nonhazardous solid waste. The existing dry scrubbing system also requires water to hydrate the lime prior to injection into the reaction modules. Based on the design of the control system, the DFGD at AVS currently use approximately 690 gpm of water. Collateral environmental impacts associated with the existing Units 1 and 2 control systems include water consumption and increased solid waste generation. There were no collateral impacts associated with the LNCFS/OFA system.

Based on a review of potential non-air quality environmental impacts, no significant collateral environmental impacts were identified for any of the SO₂ and NO_x control options included in this evaluation, with the exception, potentially, of the WFGD, TE-SCR and SNCR options. No significant non-air quality environmental impacts were identified for the options that include replacing the existing scrubber modules with new scrubber modules or FGD operational improvements/upgrades.

There are a number of potential non-air quality environmental impacts associated with the WFGD control option. Unlike dry scrubbing systems that generate a dry FGD byproduct, WFGD systems generate a liquid calcium sulfate by-product that must be dewatered prior to disposal. WFGD control systems can be designed with forced oxidation that results in a gypsum-grade by-product that can be sold into the local gypsum market. If an adequate gypsum market is not available, the gypsum by-product will require disposal. WFGD control systems also generate a wastewater stream that must be treated prior to discharge. WFGD wastewaters typically consist of a saturated solution of calcium sulfate, calcium sulfite, and sodium chloride, with trace amounts of fly ash and unreacted

limestone. Traces of metal ions may also be present due to fly ash carryover from the flue gas to the WFGD scrubber liquor. WFGD wastewater treatment systems typically require calcium sulfate/sulfite desaturation, heavy metals precipitation, coagulation/precipitation, and sludge dewatering. Treated wastewater is typically discharged to surface water pursuant to a National Pollutant Discharge Elimination System (NPDES) discharge permit, and solids are typically disposed of in a landfill. However, AVS is a zero discharge facility where only non-contact stormwater is currently discharged. With the implementation of a WFGD, the facility would need to remain a zero discharge facility.

WFGD systems also require significantly more water than the dry systems. Based on design criteria for wet and dry FGD control systems, WFGD systems typically require approximately 25-30% more water than a similarly sized DFGD control system. This would increase water consumption at each AVS Unit on average approximately 115 gpm. Water consumption is an important factor when assessing potential non-air quality environmental impacts at facilities located in North Dakota, and could represent a significant non-air quality collateral environmental impact.

In addition, the TE-SCR and SNCR control options have a number of collateral impacts. The TE-SCR catalyst oxidizes some of the SO_2 to SO_3 in addition to catalyzing the reaction between NO_x and ammonia. There could be the potential for increased SO_3 emissions with the use of a TE-SCR. The SO_3 will react with the moisture in the stack to form H_2SO_4 emissions. In addition both the TE-SCR and SNCR options utilize ammonia as the reagent for the reactions with NO_x to occur. There will be some ammonia slip emission from a TE-SCR in the range of 2 ppm. However the ammonia slip emission from a SNCR control technology will be significantly higher at 10 ppm. Ammonia slip emissions from the SNCR option will likely end up in the dry FGD solids, however there is no means to capture the ammonia slip emissions from the TE-SCR since it is installed prior to the stack. The ammoniated dry FGD solids would create a more difficult work environment for the AVS staff that would be performing maintenance on the ash handling system and performing waste disposal activities.

7.2 ENERGY IMPACTS

Options that include replacing the existing Unit 1 dry scrubbing system with a CDS/FF or WFGD system or adding a TE-SCR will increase pressure drop through the control systems, increase auxiliary power requirements, and

adversely affect the unit's net plant heat rate (Btu heat input per MW_{Net} output).⁵¹ Consequently, heat input to the boiler would need to increase to compensate for the increased auxiliary power requirements while achieving the same net plant output, or net output from the unit would decrease.

Although several of the control options have energy impacts, none of the impacts are considered significant enough as to disqualify any of the options from consideration in the four factor analysis. In order to account for potential energy impacts associated with each option, the auxiliary power cost associated with operating the control systems have been included as an annual operating cost in the economic impact assessment.

7.3 ENVIRONMENTAL / ENERGY IMPACTS SUMMARY

A summary of the Statutory Factor 3 environmental and energy impact analysis is provided in Table 7-1.

⁵¹ Heat rate represents the amount of heat input to the boiler (Btu) required to generate one megawatt (MW) net electric output and is reported as Btu/MW_{Net}.

Table 7-1. Summary of Energy and Non-Air Quality Environmental Impacts

Control Option	Collateral Environmental & Energy Impacts
Baseline	<ul style="list-style-type: none"> ➤ AVS Units 1 and 2 are currently equipped with dry scrubbing / FF control systems. Existing collateral environmental and energy impacts include: ➤ Solid FGD by-product management and disposal ➤ Increased water consumption ➤ Increased auxiliary power requirements and heat rate penalty
<u>SO₂ Control Options</u>	
Replace existing DFGD with New WFGD control system	<ul style="list-style-type: none"> ➤ Increased water consumption ➤ Wet by-product that requires dewatering prior to disposal ➤ FGD wastewater treatment & discharge ➤ Increased auxiliary power requirements and heat rate penalty

<u>NO_x Control Options</u>	
Selective Catalytic Reduction (SCR) - Tail End Configuration	<ul style="list-style-type: none"> ➤ Increased auxiliary power requirements and heat rate penalty ➤ Increased ammonia slip emissions ➤ Potential increase in SO₃ emissions
SNCR	<ul style="list-style-type: none"> ➤ Increased ammonia slip emissions ➤ Increased auxiliary power requirements and heat rate penalty ➤ Increased water consumption ➤ Increased health and safety precautions required with ammoniated dry FGD solids O&M activities.

8. REMAINING USEFUL LIFE (STATUTORY FACTOR FOUR)

The evaluation of technically feasible NO_x and SO₂ controls options should consider the source's "remaining useful life" in determining the costs of compliance. The remaining useful life is the difference between the date that controls would be put in place and the date that the facility permanently ceases operation. If the remaining useful life of the unit is shorter than the useful life of a particular control option, the remaining useful life should be used annualizing costs. If the remaining useful life exceeds the useful life of the control options, the remaining use life has no effect on the cost evaluation.

Under the current Basin Electric resource plan, the remaining useful life of AVS Units 1 and 2 are considered to be greater than 20 years. Therefore, the remaining useful life has no impact on the annualized cost of control under the current regulatory framework.

9. CONCLUSIONS

At the request of NDDH, a four factor analysis was prepared for AVS Units 1 and 2 for use in their Round II Determination. The analysis identified technically feasible SO₂ and NO_x control options for the units, and evaluated each of the control measures for the following four statutory factors:

1. The costs of compliance;
2. The time necessary for compliance;
3. The energy and non-air quality environmental impacts of compliance; and
4. The remaining useful life of any potentially affected anthropogenic source of visibility impairment.

The cost of compliance evaluation (Statutory Factor 1) prepared for SO₂ controls indicates that, from baseline emission rates, the average annual cost effectiveness of the technically feasible SO₂ control options for Unit 1 ranges from \$340 per ton (Alternative A) to \$6,992 per ton SO₂ removed (Alternative E), and for Unit 2 ranges from \$284 per ton (Alternative A) to \$6,861 per ton SO₂ removed (Alternative E). When evaluating projected future maximum emissions reductions, the average annual cost effectiveness of the technically feasible SO₂ control options for Unit 1 ranges from \$623 per ton (Alternative A) to \$6,677 per ton SO₂ removed (Alternative D), and for Unit 2 ranges from \$526 per ton (Alternative A) to \$6,584 per ton SO₂ removed (Alternative D).

The cost of compliance evaluation prepared for NO_x controls indicates that, from baseline emission rates, the average annual cost effectiveness of the technically feasible NO_x control options for Unit 1 ranges from \$19,893 per ton (Alternative A) to \$39,035 per ton NO_x removed (Alternative B), and for Unit 2 ranges from \$18,179 per ton (Alternative A) to \$36,792 per ton NO_x removed (Alternative B) from historical baselines. When evaluating projected future maximum emissions reductions, the average annual cost effectiveness of the technically feasible NO_x control options for Unit 1 ranges from \$16,667 per ton (Alternative A) to \$31,977 per ton NO_x removed (Alternative B), and for Unit 2 ranges from \$15,910 per ton (Alternative A) to \$31,589 per ton NO_x removed (Alternative B).

The time necessary for compliance (Statutory Factor 2) for the SO₂ control options ranges from 3 months (Alternative A) to 60 months (Alternative E). For NO_x control options, the time necessary for compliance ranges from 22 months (Alternative A) to 52 months (Alternative B).

An evaluation of energy impacts and non-air environmental impacts (Statutory Factor 3) indicates that certain control options will increase auxiliary power requirements due to increased pressure drop, which would adversely impact net plant heat rate. Consequently, heat input to the boiler would need to increase to compensate for the increased auxiliary power requirements while achieving the same net plant output, or net output from the unit would decrease. Collateral environmental impacts include increases in water consumption, FGD wastewater treatment and discharge, and solid waste generation.

Regarding remaining useful life (Statutory Factor 4), under the current Basin Electric resource plan, the remaining useful life of AVS Units 1 and 2 are considered to be greater than 20 years. Therefore, the remaining useful life has no impact on the annualized cost of control under the current regulatory framework.

Based on the results of the four factor analysis prepared for AVS, Basin Electric is aware that reducing SO₂ emissions by implementing FGD Operational Improvements (Alternative B) on Units 1 and 2 may be determined to be cost effective by the NDDH.

Within the Round II Determination process, the NDDH will evaluate visibility improvements relying on Western Region Area Partnership's (WRAP) cumulative modeling of the North Dakota based facilities for the various control options being evaluated. Basin Electric requests that the NDDH withhold their Round II Regional Haze SIP Determination for the AVS until the cumulative modeling platform is made available to the public and visibility improvement assessments can be conducted. Basin Electric will then perform a comparative visibility improvement analysis and submit the results to the NDDH for consideration. This effort will be coordinated with the NDDH for consistency of modeling protocols and model inputs.

In addition, Basin Electric requests, that in the event that SO₂ reductions will be required, any future 30-day rolling average permit limit will be based on an equivalent mass based combined plant (lb SO₂/hr) 30-day rolling average basis. Since AVS began operation, the current combined plant total permit limit of 3,845 lb SO₂/hr, 3-hour average, has been the benchmark for all operations guidance and procedures and is imbedded in the DFGD process control logic. To alter the basis of the operational control to a mass emission rate (lb SO₂/MMBtu) will be extremely disruptive from an operational perspective when consideration is given to the complexity and variability of DFGD operations.

The four factor analysis prepared for AVS NO_x reductions indicates that SNCR and tail-end SCR control options are cost prohibitive. The control cost evaluation indicates that the average cost effectiveness levels exceed \$15,000

per ton NO_x removed. Basin Electric is proposing that the existing OFA / LNCFS systems on Units 1 and 2 represent appropriate controls for the Round II Determination, therefore no change to the current Title V Operating Permit is proposed for NO_x emissions at AVS. Table ES-3 includes a summary of the proposed Round II Determination's control strategy for SO₂, assessed SO₂ emissions on a 30-day rolling average basis and a proposed combined plant average emission rate for AVS. The proposed emissions include compliance margin to account for items such as variability in fuel heating value and sulfur content, and operating load profile.

Table ES-1. Proposed Round II Determination's SO₂ Emission Rate

AVS Unit No.	Pollutant	Proposed Round II Determination's Emission Rate lb/MMBtu (30-day rolling average)	Proposed Round II Determination's Combined Plant Emission Rate (Note 1) (lb/hr)	Control Technology
Unit 1	SO ₂	0.30	2,958	FGD Operational Improvements
Unit 2	SO ₂	0.30	2,958	FGD Operational Improvements

Note 1. The proposed Round II Determination's combined plant emission rate is a 23% reduction from the current combined plant permit limit of 3,845 lb SO₂/hr, 3-hour avg.

APPENDIX A

NORTH DAKOTA DEPARTMENT OF HEALTH LETTER

May 2, 2018

RECEIVED MAY 04 2018

Mr. Mike Paul
Basin Electric Power Coop.
1717 E Interstate Avenue
Bismarck, ND 58503-0564

Re: Regional Haze
Second Planning Period

Dear Mr. Paul:

The Department of Health (Department) has begun work on the second planning period (Round 2) State Implementation Plan (SIP) for regional haze. In Round 1 of the regional planning process, the emphasis was on Best Available Retrofit Technology (BART) and making reasonable progress towards the national visibility goal. In Round 2, there are no BART requirements; therefore, we will focus on making reasonable progress. The reasonable progress analysis will be made using the four factors in Section 169A(g)(1) of the Clean Air Act:

The four factors are:

1. The cost of compliance
2. The time necessary to achieve compliance
3. The energy and non-air quality environmental impact of compliance; and
4. The remaining useful life of any existing source subject to such requirements

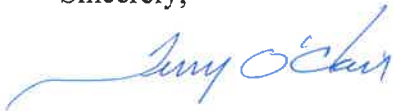

Guidance provided by the U.S. Environmental Protection Agency (Draft Guidance on Progress Tracking Metrics, Long Term Strategies, Reasonable Progress Goals and Other Requirements for Regional Haze State Implementation Plans for the Second Implementation Period at https://www.epa.gov/sites/production/files/2016-07/documents/draft_regional_haze_guidance_july_2016.pdf) indicates the Department must address 80% of the visibility impairment caused by in-state sources. Data from the IMPROVE monitoring sites at Theodore Roosevelt National Park (TRNP) and Lostwood Wilderness Area (LWA) indicate that sulfates and nitrates continue to be the largest contributors to visibility impairment in these areas. The primary precursors of sulfates and nitrates are emissions of sulfur dioxide (SO₂) and nitrogen oxides (NO_x).

Coal-fired electrical generating units have been identified as one of the largest source of sulfur dioxide and nitrogen oxides in North Dakota. Therefore, the Department requests that you prepare a "four factors" analysis for your coal-fired electrical generating units. The analysis should be prepared using the draft EPA guidance noted above. The Department will identify other sources in North Dakota that will be required to submit a four factors analysis.

The Department will be working with the Western Regional Air Partnership (WRAP) to prepare the Round 2 SIP. WRAP will be conducting air quality modeling of regional emissions reductions in early 2019. The Department asks that your "four factors" analysis be submitted by January 31, 2019.

If you have any questions, please contact David Stroh of my staff at (701)328-5188.

Sincerely,

A handwritten signature in blue ink, appearing to read "Terry O'Clair", with a long horizontal flourish extending to the left.

Terry L. O'Clair
Director
Division of Air Quality

TLO/TB:saj

Attachments: *Scubber Efficiency.pdf; image002.png;*

Erin:

I have reviewed the four factors analysis and have only a few comments:

1. On p.2-2 and Table 4-6, the design is based on all of the sulfur in the coal exiting the boiler. AP-42 indicates 25% of the sulfur in lignite is retained in the ash. This indicates the design emission rate is higher than it should be. This may effect the overall design of any new equipment (including the cost) and annual operating costs. The design sulfur emission rate should be reevaluated and appropriate revision to the analysis made.
2. On p. 4-6, it is indicated the AVS has a Plantwide Applicability Limit (PAL). AVS does not have a PAL as described in the PSD rules. The cap on three-hour SO₂ emissions is different from a PAL (annual limit). The section should be revised.
3. In Tables 4-12 and 4-13, we believe the baseline reduction of SO₂ (87%) is high. Using the AP-42 emission factor of 30(S), we believe it is around 82 - 83% (see attachment).

If you have any questions, please feel free to contact me.

NORTH DAKOTA ROUND II REGIONAL HAZE STATE
IMPLEMENTATION PLAN DETERMINATION'S FOUR-FACTOR
ANALYSIS FOR ANTELOPE VALLEY STATION
RESPONSE TO AGENCY COMMENTS

July 12, 2019
Project No. 13772-001

55 East Monroe Street • Chicago, IL 60603 USA • 312-269-2000
www.sargentlundy.com

Introduction

In January 2019, Sargent & Lundy LLC (S&L) prepared a Round II Regional Haze Four-Factor Analysis for the Antelope Valley Station (AVS) on behalf of Basin Electric Power Cooperative (Basin). The analysis was prepared in response to a request made by the North Dakota Department of Environmental Quality (NDDEQ) and included an assessment of potentially available sulfur dioxide (SO₂) and nitrogen oxide (NO_x) emission reduction technologies that could be applied to AVS Unit 1 and 2.

NDDEQ tendered comments to Basin on June 20, 2019, regarding the AVS Four-Factor Analysis. The purpose of this document is to provide responses to the June 20 comments from NDDEQ.

NDDEQ Comment 1

On p.2-2 and Table 4-6, the design is based on all of the sulfur in the coal exiting the boiler. AP-42 indicates 25% of the sulfur in lignite is retained in the ash. This indicates the design emission rate is higher than it should be. This may effect the overall design of any new equipment (including the cost) and annual operating costs. The design sulfur emission rate should be reevaluated and appropriate revision to the analysis made.

S&L/Basin Response

We appreciate the agency's comment regarding calculation of the design SO₂ inlet rate; however, adjusting the design inlet rate to account for sulfur that may be retained in the ash would not have a significant impact on either capital or O&M costs presented in the Four-Factor Analysis. S&L used projected future fuel analyses (sulfur and HHV) provided by Basin to calculate a design inlet SO₂ rate. Projections were based on the annual average fuel sulfur content and average heating value of the fuel for each year over the next 20 years, taking into account historical deviations seen in the coal quality. Coal data were provided to Basin by the Freedom Mine. The design SO₂ rate of 3.39 lb/MBtu show in Table 4-6 of the report represents the highest annual average SO₂ emission rate assuming 100% conversion of fuel sulfur to SO₂ without taking into account any inherent SO₂ retention in the ash.

It appears that NDDEQ used the Fourth Edition Compilation of Air Pollutant Emissions Factors (AP-42) from 1985 to support its comment that S&L's design SO₂ emission rate (calculated assuming 100% conversion of fuel sulfur to SO₂) is higher than it should be. That edition of AP-42 includes an assumption for lignite fuels that, on average, 75% of the fuel sulfur will be converted to SO₂ (i.e. 3.39 lb SO₂/MBtu * 0.75 = 2.54 lb SO₂/MBtu). A more recent edition recommends using an emission factor of 30S (lb/ton) for lignite-fired pulverized coal (PC) boilers, where S = weight % sulfur content of the lignite on a wet basis (see, Fifth Edition Compilation of Air Pollutant Emissions Factors AP-42, Volume 1: Stationary Point and Area Sources, Chapter 1, Table 1.7-1). A conversion factor of 0.077 is used to convert from lb/ton to lb/MBtu assuming an average lignite heating value of 6,500 Btu/lb. Using this approach, the inlet SO₂ rate would be calculated as: (30)*(1.09)*(0.077) = 2.52 lb SO₂/MBtu.

Although S&L used an uncontrolled SO₂ rate of 3.39 lb/MBtu as the design basis for the Four-Factor Analysis, that value was only used for the Projected Future Maximum Case. Uncontrolled SO₂ rates of 2.90 lb SO₂/MBtu for Units 1 and 2 (see Table 4-4 of the Four Factor Analysis) were used for the Actual Average Case.

When reviewing the technically feasible SO₂ alternatives for the AVS station, costs associated with the DFGD upgrades are primarily O&M driven. Variable O&M costs for DFGD operational changes are predominantly a function of the lime consumption rate. Lime consumption rates were based on an uncontrolled SO₂ rate of 2.90 lb SO₂/MBtu for the Actual Average Case. Revising the uncontrolled emission rate to 2.54 lb SO₂/MBtu would reduce the lime consumption rate by approximately 15%; however, they would be a corresponding reduction in the quantity of SO₂ removed such that the change would not have an impact on the cost-effectiveness analysis.

For the capital driven SO₂ alternatives (i.e., new DFGD or new WFGD), capital costs are predominantly driven by the absorber size which is based on the flue gas volumetric flow rate rather than inlet SO₂ concentration. As such, the difference between designing new equipment for 2.54 lb SO₂/MBtu and 2.90 lb SO₂/MBtu will not have a significant impact on the cost-effectiveness analysis because the capital costs would essentially be the same.

NDDEQ Comment 2

On p. 4-6, it is indicated the AVS has a Plantwide Applicability Limit (PAL). AVS does not have a PAL as described in the PSD rules. The cap on three-hour SO₂ emissions is different from a PAL (annual limit). The section should be revised.

S&L/Basin Response

We will revise the section accordingly. Previous terminology that was used will be adjusted as follows: “AVS Units 1 and 2 have a combined 3-hour SO₂ ~~plantwide-applicability limit (PAL)~~ of 3,845 lb/hr in their Title V Air Permit that allows the station to adjust operation of each unit’s FGD system as long as they achieve the combined overall-plantwide limit.”

NDDEQ Comment 3

In Tables 4-12 and 4-13, we believe the baseline reduction of SO₂ (87%) is high. Using the AP-42 emission factor of 30(S), we believe it is around 82 - 83% (see attachment).

S&L/Basin Response

We agree that the existing DFGD alone may provide a removal efficiency of approximately 82-83%, while the coal-to-stack removal efficiency is closer to 87%. Removal efficiencies listed in Table 4-12 and 4-13 were calculated based on the controlled SO₂ emission rate achieved with each technology and assuming an inlet SO₂ rate of 2.90 lb/MBtu (see response to Comment 1). Removal efficiencies in Table 4-12 and 4-13 represent overall SO₂ removal and are provided for comparative purposes. However, it is important to note that the baseline SO₂ emission rates (in tpy) were not calculated using an uncontrolled emission rate of 2.90 lb SO₂/MBtu; instead it was calculated based on the historic annual heat input and stack emission rate. Therefore, reducing the uncontrolled SO₂ rate, or adjusting the removal efficiencies, would not have an impact on the tons of SO₂ removed or the cost-effectiveness analysis.

Re: Regional Haze
Second Planning Period

Dear Mr. Paul:

The Department of Health (Department) has begun work on the second planning period (Round 2) State Implementation Plan (SIP) for regional haze. In Round 1 of the regional planning process, the emphasis was on Best Available Retrofit Technology (BART) and making reasonable progress towards the national visibility goal. In Round 2, there are no BART requirements; therefore, we will focus on making reasonable progress. The reasonable progress analysis will be made using the four factors in Section 169A(g)(1) of the Clean Air Act:

The four factors are:

1. The cost of compliance
2. The time necessary to achieve compliance
3. The energy and non-air quality environmental impact of compliance; and
4. The remaining useful life of any existing source subject to such requirements

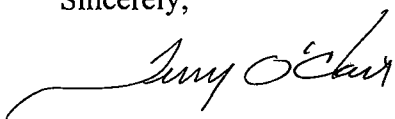

Guidance provided by the U.S. Environmental Protection Agency (Draft Guidance on Progress Tracking Metrics, Long Term Strategies, Reasonable Progress Goals and Other Requirements for Regional Haze State Implementation Plans for the Second Implementation Period at https://www.epa.gov/sites/production/files/2016-07/documents/draft_regional_haze_guidance_july_2016.pdf) indicates the Department must address 80% of the visibility impairment caused by in-state sources. Data from the IMPROVE monitoring sites at Theodore Roosevelt National Park (TRNP) and Lostwood Wilderness Area (LWA) indicate that sulfates and nitrates continue to be the largest contributors to visibility impairment in these areas. The primary precursors of sulfates and nitrates are emissions of sulfur dioxide (SO₂) and nitrogen oxides (NO_x).

Coal-fired electrical generating units have been identified as one of the largest source of sulfur dioxide and nitrogen oxides in North Dakota. Therefore, the Department requests that you prepare a "four factors" analysis for your coal-fired electrical generating units. The analysis should be prepared using the draft EPA guidance noted above. The Department will identify other sources in North Dakota that will be required to submit a four factors analysis.

The Department will be working with the Western Regional Air Partnership (WRAP) to prepare the Round 2 SIP. WRAP will be conducting air quality modeling of regional emissions reductions in early 2019. The Department asks that your "four factors" analysis be submitted by January 31, 2019.

If you have any questions, please contact David Stroh of my staff at (701)328-5188.

Sincerely,

Terry L. O'Clair
Director
Division of Air Quality

B.3.b – Facility Response

January 31, 2019

Mr. Terry O'Clair
North Dakota Department of Health
918 East Divide Avenue, Second Floor
Bismarck, ND 58501-1947

Dear Mr. O'Clair:

RE: Four Factor Analysis Submittal for Antelope Valley Station and Leland Olds Station

Enclosed, you will find one CD and three hard copies of Basin Electric Power Cooperative's (**Basin Electric**) Round II Regional Haze Determination Four Factor Analysis for the Antelope Valley and Leland Olds Stations. This analysis was performed as outlined in the North Dakota Department of Health's (**NDDH**) May 2, 2018, request. Basin Electric is aware that the four factor analysis is one component contributing to the NDDH's Round II Regional Haze State Implementation Plan's Determination for each of these emission sources.

North Dakota is relying on the Western Regional Air Partnership (**WRAP**) to develop the visibility modeling platform needed to evaluate visibility at the Class I areas and subsequently for the individual states to develop and assess compliance strategies that will be formalized within the Round II Regional Haze State Implementation Plan.

Basin Electric requests that the NDDH withhold its Round II Regional Haze Determination until a comparative evaluation of visibility from the various control alternatives have been performed. The timing of the visibility analysis is subject to model availability. Basin Electric will continue to monitor WRAP's model development and will coordinate closely with the NDDH prior to initiating visibility impact analysis.

Should you have any questions concerning this submittal, please do not hesitate to contact Erin Dukart, Environmental Compliance Administrator at edukart@bepc.com or 701.557.5557.

Sincerely,

Mike Paul
Chief Technical Advisor

EXECUTIVE SUMMARY

The Leland Olds Station (LOS), located near Stanton, ND, has two generating units (Units 1 and 2) rated at 220 MW and 440 MW, respectively. Both units are designed to fire North Dakota lignite coal. LOS Unit 1 is a B&W opposed wall-fired unit that went online in 1966. LOS Unit 1 is equipped with an Emerson combustion optimizers, low-NO_x burners (LNB), advanced separated overfire air (SOFA) and selective non-catalytic reduction (SNCR) for nitrogen oxide (NO_x) control, wet limestone flue gas desulfurization (WFGD) system for sulfur dioxide (SO₂) control, and electrostatic precipitators (ESP) for particulate matter (PM) control. LOS Unit 2 is a B&W cyclone-fired unit that went online in 1975. LOS Unit 2 is equipped with an Emerson combustion optimizer, SOFA, and SNCR for NO_x control, WFGD for SO₂ control, and ESP for PM control.

On July 1, 1999, the U.S. Environmental Protection Agency (EPA) published regulations implementing Section 169A of the Clean Air Act (CAA), establishing a comprehensive visibility protection program for Federal Class I areas (the Regional Haze Rule).¹ The Regional Haze Rule requires each state to develop, and submit for approval by EPA, a state implementation plan (SIP) detailing the state's plan to protect visibility in Class I areas. The Regional Haze Rule established a schedule setting forth deadlines by which the states must submit their initial regional haze SIPs and subsequent revisions to the SIPs. Regional Haze SIPs for the initial planning period were due in 2007, with subsequent SIP updates due in 2018 and every 10 years thereafter.²

During the initial planning period, the North Dakota Department of Health (NDDH) concluded that best available retrofit technology (BART) for both of Basin Electric Cooperative's (Basin Electric) LOS units included new WFGDs for SO₂ control and SOFA with SNCR for NO_x control. U.S. EPA initially disapproved NDDH's determination for LOS Unit 2 NO_x emissions, and issued a proposed a Federal Implementation Plan (FIP) that included advanced SOFA plus selective catalytic reduction (SCR). Following the public notice and comment period for the proposed FIP, EPA reversed its position regarding the technical feasibility of SCR on LOS Unit 2 and decided to approve the State's BART determination for NO_x control on LOS Unit 2.

¹ 64 FR 35713

² On January 10, 2017, EPA made a one-time adjustment to the due date for the second implementation period (2018 – 2028) by extending the deadline from July 31, 2018 to July 31, 2021 (82 FR 3078).

As part of the Round II Regional Haze State Implementation Plan Determination (Round II Determination), NDDH requested that Basin Electric prepare a four-factor analysis of SO₂ and NO_x emissions control options for LOS Units 1 and 2. The analysis evaluates technically feasible SO₂ and NO_x emission reduction measures for the following four statutory factors:

- Factor 1: The cost of compliance
- Factor 2: The time necessary to achieve compliance
- Factor 3: The energy and non-air quality environmental impact of compliance
- Factor 4: The remaining useful life of any existing source subject to such requirements

Sargent & Lundy LLC (S&L) and Basin Electric evaluated potentially available SO₂ and NO_x emissions reduction options for LOS Units 1 and 2 to identify technically feasible control options for inclusion in the four factor analysis. The SO₂ and NO_x control options included in this four factor analysis are identified in Table ES-1 and Table ES-2.

Table ES-1. Technically Feasible SO₂ Control Options

LOS Unit 1		LOS Unit 2	
Alt. No.	SO ₂ Control Technology	Alt. No.	SO ₂ Control Technology
B	FGD Upgrades – pH Buffer Addition	B	FGD Upgrades – pH Buffer Addition
A	FGD Operational Improvements – Ca:S Stoichiometry	A	FGD Operational Improvements – Ca:S Stoichiometry and Liquid-to-Gas Ratio
--	Baseline (existing WFGD)	--	Baseline (existing WFGD)

Table ES-2. Technically Feasible NO_x Control Options

LOS Unit 1		LOS Unit 2	
Alt. No.	NO _x Control Technology	Alt. No.	NO _x Control Technology
		B	Optimized SNCR + rich reagent injection (RRI)
A	SCR – tail-end configuration ^(Note 1)	A	Optimized SNCR
--	Baseline (existing LNB / SOFA / SNCR)	--	Baseline (existing LNB / SOFA / SNCR)

Note 1. Tail-end SCR (TE-SCR) has not been installed on a North Dakota lignite-fired unit, and extended trials would be needed to better understand the design and operation of TE-SCR on LOS Unit 1. Nevertheless, during the initial planning period, NDDH concluded that TE-SCR was a technically feasible NO_x control technology for a North Dakota lignite-fired boiler, and evaluated the costs and cost-effectiveness of the control system. For consistency with NDDH's conclusion from the first planning period, TE-SCR will be carried forward to the Four Factor Analysis.

The cost of compliance evaluation (Statutory Factor 1) prepared for SO₂ controls indicates that, from baseline emission rates, the average annual cost effectiveness of the technically feasible SO₂ control options for Unit 1 ranges from \$10,021 per ton (Alternative A) to \$17,948 per ton SO₂ removed (Alternative B), and for Unit 2 ranges from \$6,906 per ton (Alternative A) to \$13,946 per ton SO₂ removed (Alternative B). When evaluating projected future maximum emissions reductions, the average annual cost effectiveness of the technically feasible SO₂ control options for Unit 1 ranges from \$18,200 per ton (Alternative A) to \$18,948 per ton SO₂ removed (Alternative B), and for Unit 2 ranges from \$13,444 per ton (Alternative A) to \$15,462 per ton SO₂ removed (Alternative B).

The cost of compliance evaluation prepared for NO_x controls indicates that, from baseline emission rates, the average annual cost effectiveness of the technically feasible NO_x control options for Unit 1 is \$54,605 per ton NO_x removed (Alternative A), and for Unit 2 ranges from \$1,896 per ton (Alternative A) to \$3,630 per ton NO_x removed (Alternative B). When evaluating projected future maximum emissions reductions, the average annual cost effectiveness of the technically feasible NO_x control options for Unit 1 is \$28,528 per ton NO_x removed (Alternative A), and for Unit 2 ranges from \$1,588 per ton (Alternative A) to \$3,186 per ton NO_x removed (Alternative B). For Unit 2, Alternatives A and B will also affect the units' net plant heat rate since the amount of water that will be injected with the urea will negatively impact boiler efficiency. Both alternatives do not include additional costs that would be incurred due to the loss in net generation.

The time necessary for compliance (Statutory Factor 2) for the SO₂ control options ranges from 3 months (Alternative A) to 12 months (Alternative B). For NO_x control options, the time necessary for compliance ranges from 12 months (Alternatives A and B – Unit 2) to 52 months (Alternative A – Unit 1).

An evaluation of energy impacts and non-air environmental impacts (Statutory Factor 3) indicates that certain control options will increase auxiliary power requirements due to increased pressure drop, which would adversely impact net plant heat rate. Consequently, heat input to the boiler would need to increase to compensate for the increased auxiliary power requirements while achieving the same net plant output, or net output from the unit would decrease. Collateral environmental impacts potential include increases in water consumption, solid waste generation, sulfuric acid mist emissions, and ammonia emissions.

Regarding remaining useful life (Statutory Factor 4), under the current Basin Electric resource plan, the remaining useful life of LOS Unit 1 and 2 are considered to be greater than 20 years. Therefore, the remaining useful life has no impact on the annualized cost of control under the current regulatory framework.

Based on the results of the four factor analysis prepared for LOS SO₂ emissions reductions, WFGD Operational Improvements and WFGD Upgrades are cost prohibitive. The control cost evaluation indicates that the average cost effectiveness levels exceed \$6,900 per ton SO₂ removed. Therefore, Basin Electric is proposing that the existing WFGD systems on Units 1 and 2 represent appropriate controls for the Round II Determination.

The four factor analysis prepared for LOS Units 1 indicates that additional NO_x controls are cost prohibitive. The cost effectiveness of installing a TE-SCR system on Unit 1 is over \$28,000 per ton NO_x removed. Therefore, Basin Electric is proposing that the existing LNB / SOFA / SNCR system on Unit 1 represents appropriate controls for the Round II Determination. For Unit 2, the analysis indicates a cost effectiveness of \$1,600 ton for the optimized SNCR alternative. The implementation of the optimized SNCR decreases the actual hourly mass emission rate by approximately 100 lb per hr (from historical baseline emissions). However, it can increase ammonia emissions, and that effect would result in additional haze formation. As such, a 5th factor analysis (visibility improvement using modeling) is recommended for this option to determine whether there is any or only a trivial amount of visibility improvement. Basin Electric requests that the NDDH withhold their Round II Determination until the Western Region Area Partnership's cumulative modeling platform are available so that a visibility improvement assessment can be conducted. Basin Electric will then perform a comparative visibility improvement analysis between the two control alternatives and submit the results to the NDDH for consideration.

It is generally understood from previous visibility modeling efforts that increased ammonia injection has the opportunity of providing additional ammonia to the atmosphere. This increased ammonia availability within the emitted plume itself is known to contribute to increased visibility impairment due to more direct formation of ammonium sulfate and ammonium nitrate, especially in the winter months where fine particulate formation is ammonia limited. In fact, it is during the winter months that the NO_x emissions have a visibility effect; the observed (and modeled) nitrate haze during the warmer months with more park visitation is negligible. As a result of the future modeling analysis, the actual visibility benefit of the optimized SNCR alternative may be considered minimal if not de-minimis.

For the Round II Determination, no change to the current Title V Operating Permit is proposed for SO₂ emissions on either LOS Unit 1 or 2 and no proposed change to the NO_x emissions on LOS Unit 1. Table ES-3 includes a summary of the proposed Round II Determination's strategy for NO_x, assessed NO_x emissions on a 30-day rolling average basis and a proposed Round II Determination's emission rate on a 30-day rolling average basis for LOS

Unit 2. The proposed emissions limits include compliance margin to account for items such as variability in the operating load profile.

Table ES-3. Proposed Round II Determination's NO_x Emission Rate

LOS Unit No.	Pollutant	Assessed Emission Rate lb/MMBtu ^(Note 2) (30-day rolling average)	Proposed Round II Determination's Emission Rate lb/MMBtu ^(Note 1) (30-day rolling average)	Control Technology
Unit 2	NO _x	0.27	0.30	Optimized SNCR System

Note 1. The proposed Round II Determination's emission rate is a 14% reduction from the current permit limit of 0.35 lb NO_x/MMBtu, 30-day rolling avg.

Note 2. The assessed emission rate represents the average emission rate that LOS Unit 2 would be expected to achieve on an on-going long-term basis under normal operating conditions.

1. INTRODUCTION

Sargent & Lundy, L.L.C. (S&L) was retained by Basin Electric Power Cooperative (Basin Electric) to prepare a Round II Regional Haze State Implementation Plan Determination's (Round II Determination) four-factor analysis for the control of sulfur dioxide (SO₂) and nitrogen oxide (NO_x) emissions from Basin Electric's Leland Olds Station (LOS) Units 1 and 2. This evaluation is in response to the North Dakota Department of Health's formal letter dated May 2, 2018, attached in Appendix A. The evaluation includes an assessment of potentially available emission reduction measures for the four statutory factors listed in 40 CFR 51.308(f)(2), and takes into consideration U.S. Environmental Protection Agency's (EPA's) *Draft Guidance on Progress Tracking Metrics, Long Term Strategies, Reasonable Progress Goals and Other Requirements for Regional Haze State Implementation Plans for the Second Implementation Period* (the "Draft EPA Guidance").³ Technically feasible SO₂ and NO_x emission reduction measures are evaluated for the following four statutory factors:

- Factor 1: The cost of compliance
- Factor 2: The time necessary to achieve compliance
- Factor 3: The energy and non-air quality environmental impact of compliance
- Factor 4: The remaining useful life of any existing source subject to such requirements

The Round II Determination's four factor analysis for LOS Units 1 and 2 is presented in the following sections:

- Section 2: Facility Description** contains information describing the facility, site location, and existing equipment.
- Section 3: Four-Factor Analysis Requirements** provides a brief description of the Regional Haze Program requirements set forth in 40 CFR 51.308.
- Section 4: SO₂ Control Evaluation** establishes representative baseline SO₂ emissions, identifies potentially available emission control technologies, evaluates each control option for technical feasibility and evaluates cost effectiveness of technically feasible control options.

³ On September 11, 2018, EPA released a "*Regional Haze Reform Roadmap*" announcing its plan to "release a series of implementation tools and guidance documents that will help focus states' efforts and reduce and streamline the time and resources needed to meet the statutory and regulatory requirements for reducing regional haze in National Parks, wildlife refuges, and wilderness areas." EPA stated that it plans to issue a new guidance document on Regional Haze SIP Development by Spring, 2019. Basin Electric reserves the right to update and modify this four-factor analysis, as needed, to be consistent with any new guidance issued by the agency.

- Section 5:** **NO_x Control Evaluation** establishes representative baseline NO_x emissions, identifies potentially available emission control technologies, evaluates each control option for technical feasibility and evaluates cost effectiveness of technically feasible control options.
- Section 6:** **Time Necessary for Compliance (Statutory Factor Two)** provides typical timelines required to design, engineer, procure and install the technically feasible control options.
- Section 7:** **Energy and Non-Air Quality Environmental Impacts (Statutory Factor Three)** identifies the energy and non-air quality environmental impacts associated with each technically feasible control option.
- Section 8:** **Remaining Useful Life (Statutory Factor Four)** includes a discussion of the planned remaining useful life of LOS Units 1 and 2, including an evaluation of how remaining useful life affects the cost-effectiveness of each technically feasible control option.
- Section 9:** **Summary and Conclusions**

Appendix C: SO₂ Control Cost Effectiveness Estimates

Appendix D: NO_x Control Cost Effectiveness Estimates

2. FACILITY DESCRIPTION

The Leland Olds Station (LOS), located near Stanton, ND, has two generating units (Units 1 and 2) rated at 220 MW and 440 MW, respectively. Both units are designed to fire North Dakota lignite coal. LOS Unit 1 is a Babcock and Wilcox (B&W) opposed wall-fired unit that went online in 1966. LOS Unit 1 is equipped with an Emerson combustion optimizer, low-NO_x burners (LNB), advanced separated overfire air (SOFA) and selective non-catalytic reduction (SNCR) for NO_x control, wet limestone flue gas desulfurization (WFGD) system for SO₂ control, and electrostatic precipitators (ESP) for particulate matter (PM) control. LOS Unit 2 is a B&W cyclone-fired unit that went online in 1975. LOS Unit 2 is equipped with an Emerson combustion optimizer, SOFA, and SNCR for NO_x control, WFGD for SO₂ control, and ESP for PM control.

Table 2-1 provides a summary of the design parameters used for the LOS Units 1 and 2 four factor analysis. The four factor analysis design parameters listed in Table 2-1 were developed from information provided by Basin Electric.

Table 2-1. Four Factor Analysis Design Basis Parameters

Parameter	LOS Unit 1	LOS Unit 2
Boiler type	PC opposed wall-fired	Cyclone-fired
Boiler manufacturer	B&W	B&W
Generating Capacity (MWg)	220	440
Design heat input (MMBtu/hr)	2,622	5,130
Average Hourly Heat Input for Baseline SO ₂ period (MMBtu/hr)	1,851	3,779
Capacity Factor for Baseline SO ₂ period (%)	68	69
Average Hourly Heat Input for Baseline NO _x period (MMBtu/hr)	1,646	3,692
Capacity Factor for Baseline NO _x period (%)	51	68
Full load flue gas conditions at WFGD Outlet		
Temperature (°F)	145	144

NORTH DAKOTA ROUND II STATE IMPLEMENTATION PLAN
 DETERMINATION'S FOUR-FACTOR ANALYSIS FOR LELAND OLDS
 UNITS 1 AND 2

2-2

Parameter	LOS Unit 1	LOS Unit 2
Mass flow rate (lb/hr)	3,028,000	6,396,000
Volumetric flow rate (acfm)	816,500	1,722,500
Baseline Fuel Parameters ⁽¹⁾		
Higher Heating Value (Btu/lb)	6,793	6,818
Fuel sulfur content (%)	1.06	1.04
SO ₂ content (lb/MMBtu)	3.12	3.05
Projected Future Fuel Parameters ⁽²⁾		
Higher Heating Value (Btu/lb)	6,595	
Fuel sulfur content (%)	1.23	
SO ₂ content (lb/MMBtu)	3.73	

Note 1. Current fuel parameters are based on the actual annual average fuel sulfur content from 2014-2018 provided by Basin Electric.

Note 2. Projected future fuel parameters are based on anticipated annual average coal projections provided by Basin Electric from 2019-2040. Projected future sulfur and SO₂ content includes margin based on the actual deviation in annual average sulfur content from current coal data. Additional detail on coal sulfur provided in Section 4.2.

3. FOUR-FACTOR ANALYSIS REQUIREMENTS

3.1 REGIONAL HAZE RULE BACKGROUND

Section 169A of the 1977 Amendments to the Clean Air Act (CAA) sets forth a program for protecting visibility in Federal Class I areas which calls for “the prevention of any future, and the remedying of any existing, impairment of visibility in mandatory Federal Class I areas which impairment results from manmade air pollution.” Federal Class I areas include national parks, memorial parks, and wilderness areas over a certain size. Figure 3-1 shows the locations of the 156 federally mandated Class I areas. Federal Class I areas located within North Dakota include the Theodore Roosevelt National Park and the Lostwood National Wildlife Refuge.

Figure 3-1. Federal Class I Areas

On July 1, 1999, the U.S. EPA published regulations implementing Section 169A of the CAA, establishing a comprehensive visibility protection program for Federal Class I areas (the Regional Haze Rule).⁴ The Regional Haze Rule requires each state to develop, and submit for approval by EPA, a state implementation plan (SIP) detailing the state's plan to protect visibility in Class I areas. Regional Haze SIPs must contain such emission limits, schedules of compliance, and other measures as may be necessary to make reasonable progress toward meeting the national visibility goal of achieving visibility in Class 1 areas which reflects natural conditions by 2064.

To address the combined visibility effects of various pollution sources over a wide geographic region, EPA designated five Regional Planning Organizations (RPOs) to assist with the coordination and cooperation needed to address the visibility issue. The five RPOs are shown in Figure 3-2. North Dakota is a member of the Western Regional Air Partnership (WRAP), which serves as the RPO for visibility protection at 118 Class I areas in 15 western states.

Figure 3-2. Regional Planning Organization Map

⁴ 64 FR 35713

3.1.1 First Implementation Period

The Regional Haze Rule established a schedule setting forth deadlines by which the states must submit their initial regional haze SIPs and subsequent revisions to the SIPs. Regional Haze SIPs for the initial planning period were due in 2007, with subsequent SIP updates due in 2018 and every 10 years thereafter.⁵

Regional Haze SIP requirements for the first planning period required that states incorporate into their plans the core program requirements in 40 CFR 51.308(d), including: (1) establishing reasonable progress goals (RPGs) for each Class I area within the state that provide for measurable progress towards achieving natural visibility conditions; (2) developing a long-term strategy (LTS) including enforceable emissions limitations and compliance schedules to achieve the RPGs; and (3) developing plans to monitor and assess the effectiveness of the LTS to achieve the RPGs over the prior implementation period and affirmation of or revision to the RPGs.

The Regional Haze Rule requires that states determine the consistent rate of progress over time needed to attain natural visibility conditions on the 20 percent most impaired days by the year 2064. This “glidepath” is referred to as the uniform rate of progress (URP) line. States must consider the URP, and the emission reduction measures needed to achieve this level of improvement, when developing their RPGs and LTS. Regulations at 40 CFR 51.308(g) require each state to submit progress reports, in the form of SIP revisions, every 5 years following the submission of the initial SIP. These progress reports must evaluate the progress made towards the RPGs for Class I areas located within the state as well as those Class I areas located outside the state that may be affected by emissions from within the state.

3.1.1.1 Best Available Retrofit Technology

As a one-time requirement during the first implementation period, potential best available retrofit technology (BART) controls had to be evaluated for certain large stationary sources. States were required to conduct BART determinations for “BART-eligible” sources anticipated to cause or contribute to any visibility impairment in one or more Class I area. BART-eligible sources included coal-fired electric generating units (EGUs) that were in existence on August 7, 1977, but not in operation prior to August 7, 1962. As an alternative to requiring source-

⁵ On January 10, 2017, EPA made a one-time adjustment to the due date for the second implementation period (2018 – 2028) by extending the deadline from July 31, 2018 to July 31, 2021 (82 FR 3078).

specific BART controls, states also had the flexibility to adopt an emissions trading program or other alternative program as long as the alternative provided greater reasonable progress towards improving visibility than BART.

3.1.1.2 North Dakota's Initial Planning Period SIP

The State of North Dakota submitted its regional haze SIP addressing the requirements of 40 CFR 51.308 to EPA for review on March 3, 2010 (the "Regional Haze SIP").⁶ The Regional Haze SIP was prepared by the North Dakota Department of Health, Air Quality Division (NDDH). The SIP included BART determinations for seven steam EGUs identified as being subject to the BART requirements of 40 CFR 51.208(e) and a reasonable progress evaluation for six additional non-BART sources identified as having the potential to affect visibility in a Class I area.

Basin Electric's LOS Units 1 & 2 were evaluated by NDDH as subject-to-BART sources.⁷ Based on its evaluation of available control technologies, NDDH concluded that BART for both LOS units included new WFGD for SO₂ control and SOFA with SNCR for NO_x control. NDDH determined that selective catalytic reduction (SCR), a higher performing NO_x control option, was not an available, and thus not a technically feasible, NO_x control option.⁸

Basin Electric's AVS Units 1 & 2 were evaluated by NDDH under the reasonable progress requirements. Based on an evaluation of the four reasonable progress statutory factors (i.e., costs of compliance, time necessary for compliance, energy and non-air quality environmental impacts of compliance, and the remaining useful life of the units) plus an evaluation of incremental visibility improvement, NDDH concluded that requiring additional controls (beyond those required for the BART-eligible sources) would not substantially improve visibility in the Class I

⁶ North Dakota State Implementation Plan for Regional Haze – A Plan for Implementing the Regional Haze Program Requirements of Section 308 of 40 CFR Part 51, Subpart P – Protection of Visibility, North Dakota Department of Health, February 24, 2010. In addition to the initial SIP submittal, the State submitted a SIP Supplement No. 1 on July 27, 2010, and a SIP Amendment No. 1 on July 28, 2011 (collectively the "Regional Haze SIP").

⁷ In addition to LOS Units 1 & 2, NDDH evaluated Great River Energy's Coal Creek Station Units 1 & 2; Great River Energy's Stanton Station Unit 1; and Minnkota Power Cooperative's Milton R. Young Station Units 1 & 2 as subject-to-BART sources.

⁸ Regional Haze SIP, pg. 73. The State's evaluation of SCR for North Dakota lignite was included as Appendix B.5 to the Regional Haze SIP (Best Available Retrofit Technology – Selective Catalytic Reduction Technical Feasibility Analysis for North Dakota Lignite, July 2009). NDDH eliminated SCR from consideration as BART based on a finding that SCR was not technically feasible to control emissions from North Dakota lignite coal. In particular, NDDH noted that no SCR has ever been employed on an EGU burning North Dakota lignite, that North Dakota lignite has unique properties that have the potential to quickly degrade the SCR catalyst, and that no catalyst vendor would provide a guarantee of catalyst life without first conducting slipstream or pilot testing.

areas, and that for all reasonable progress sources evaluated individually and cumulatively, control technology costs (evaluated on a dollar per deciview improvement (\$/dv) basis) was excessive. Therefore, the Regional Haze SIP did not include additional control for AVS Units 1 & 2.⁹

On September 21, 2011, EPA published a Proposed Rule proposing to partially approve and partially disapprove specific aspects the Regional Haze SIP.¹⁰ Among other things, EPA proposed to disapprove the State's determination of BART for LOS Unit 2 as well as the reasonable progress determination for AVS Units 1 & 2. EPA proposed to approve the remaining aspects of North Dakota's Regional Haze SIP, including that State's BART determination for SO₂ control at LOS (i.e., new WFGD) and the NO_x BART determination for LOS Unit 1 (i.e., SOFA+SNCR).¹¹ Along with the proposed partial disapproval of North Dakota's SIP, EPA proposed the promulgation of a Federal Implementation Plan (FIP). The proposed FIP included, among other items: (1) a NO_x BART determination and emission limits for LOS Unit 2; and (2) a reasonable progress determination and NO_x emission limits for AVS Units 1 & 2. EPA proposed advanced SOFA (ASOFA) plus SCR and an emission rate of 0.07 lb/MMBtu (30-day rolling average) as BART for NO_x control on LOS Unit 2. EPA also proposed LNB plus SOFA and an emission limit of 0.17 lb/MMBtu (30-day rolling average) as representing reasonable progress NO_x control on AVS Units 1 & 2.¹²

Following the public notice and comment period EPA issued its Final Rule on April 6, 2012.¹³ The Final Rule differed from the Proposed Rule in that EPA reversed its position regarding the technical feasibility of SCR on LOS

⁹ *Id.* at pg. 188.

¹⁰ 76 Fed. Reg. 58570, September 21, 2011 (the "Proposed FIP"). In addition to the proposed disapproval of the State's BART determination for Leland Olds Station Unit 2, EPA proposed disapproving the BART determinations for the Coal Creek Station and Milton R. Young Station (MRYS) Units 1 & 2.

¹¹ *Id.* at pg. 58619. Note that for LOS Unit 1 EPA stated that it did not agree with the State's cost analysis for SCR, but nonetheless found the elimination of SCR for LOS Unit 1 to be acceptable because LOS Unit 1 is relatively small (216 MW) compared to LOS Unit 2 (440 MW) and MRYS Units 1 & 2, and LOS Unit 1 had lower baseline NO_x emission. (76 FR 58596, Table 22).

¹² *Id.* at pg. 58632. EPA eliminated higher performing NO_x control options for AVS Units 1 & 2, including LNB + SNCR; SCR; and LNB + SCR, because their cost effectiveness values were significantly higher and/or the emission reductions were not that much higher than LNB. Considering the statutory factors, EPA found that it was not reasonable to insist on these higher control levels in the first; however, EPA noted that expected North Dakota to consider such controls in the next planning period.

¹³ 77 Fed. Reg. 20894.

Unit 2 and decided to approve the State's BART determination for NO_x control on LOS Unit 2.¹⁴ Conversely, EPA finalized its determination that LNB+SOFA was required by reasonable progress for AVS Units 1 & 2.

EPA's decision to accept the BART determinations for LOS Unit 2 (and Minnkota Power Cooperative Inc.'s Milton R. Young Station (MRYS) Units 1 & 2) was based primarily on the decision in United States v. Minnkota Power Cooperative, Inc.¹⁵ which concluded that the State's best available control technology (BACT) analysis for NO_x control on MRYS Units 1 & 2 was not unreasonable, a conclusion that was contrary to EPA's position at the time of the Proposed FIP.¹⁶ In explaining its decision to reverse its position that SCR was a technically feasible NO_x control option for LOS Unit 2, EPA noted that the technical feasibility determination under the BACT and BART analyses was substantially the same, and that the BART Guidelines permit a state to rely upon a BACT determination for purposes of selecting BART unless new technologies have become available or best control levels for recent retrofits have become more stringent.¹⁷ Noting that the District Court upheld North Dakota's BACT determination for MRYS Units 1 & 2, EPA concluded that it would be inappropriate to proceed with its proposed disapproval of SNCR as BART, and approved the State's determination that ASOFA+SNCR and an emission rate of 0.35 lb/MMBtu (30-day rolling average) was BART for NO_x control on LOS Unit 2.

Emission controls required by the Regional Haze SIP for the Basin Electric's LOS and AVS stations are summarized in Table 3-1.

¹⁴ *Id.* at pg. 20897-98. EPA also reversed its position and decided to approve the State's BART determination for NO_x control on MRYS Units 1 & 2.

¹⁵ United States v. Minnkota Power Cooperative, Inc., 831 F. Supp. 2d 1109, 1127-30 (D.N.D. 2011).

¹⁶ Contemporaneous with the Regional Haze SIP/FIP process, NDDH was also determining BACT for MRYS Units 1 & 2 pursuant to a Consent Decree entered into between the owner of the station (Minnkota), the State, and EPA under the CAA's Prevention of Significant Deterioration program. In its BACT analysis, NDDH concluded that SCR was technically infeasible on a lignite-fired cyclone boiler, and selected SNCR as BACT. EPA challenged the State's BACT determination in district court, contending that SCR was a technically feasible emission control option and should have been selected as BACT. On December 21, 2011, the District Court issued its decision on EPA's challenge of the State's BACT determination, finding that the State's conclusion that SCR was not technically feasible was not unreasonable. See, *U.S. v. Minnkota*, 831 F. Supp. 2d at 1127-30.

¹⁷ 77 Fed. Reg. 20897.

Table 3-1. Initial Planning Period SIP Summary

Source & Unit	Pollutant	Control Device / Emission Limit
LOS Unit 1 (BART)	NO _x	Basic SOFA + SNCR with an emission limit of 0.19 lb/MMBtu (30-day rolling average)
	SO ₂	New WFGD operating at 95% efficiency or below an emission limit of 0.15 lb/MMBtu (30-day rolling average)
LOS Unit 2 (BART)	NO _x	Advanced SOFA + SNCR with an emission limit of 0.35 lb/MMBtu (30-day rolling average)
	SO ₂	New WFGD operating at 95% efficiency or below an emission limit of 0.15 lb/MMBtu (30-day rolling average)
AVS Unit 1 (reasonable progress)	NO _x	LNB + SOFA with an emission limit of 0.17 lb/MMBtu (30-day rolling average)
	SO ₂	No additional control beyond the existing dry FGD / baghouse
AVS Unit 2 (reasonable progress)	NO _x	LNB + SOFA with an emission limit of 0.17 lb/MMBtu (30-day rolling average)
	SO ₂	No additional control beyond the existing dry FGD / baghouse

3.1.1.3 BART Requirements for Leland Olds Station during First Planning Period

LOS Unit 1 and 2 commenced operation in 1966 and 1975, respectively; thus, both units were subject to BART requirements during the first planning period. The BART selected by NDDH for LOS Unit 1 and Unit 2 was WFGD for SO₂ control and SOFA and SNCR for NO_x control with a compliance date of April 4, 2017.

A 0.15 lb SO₂/MMBtu or 95% SO₂ removal on a 30-day rolling average limit was placed on each LOS Unit, which corresponds with the Presumptive BART SO₂ control level proposed by EPA for a WFGD. A NO_x limit of 0.19 lb/MMBtu and 0.35 lb/MMBtu on a 30-day rolling average was placed on LOS Unit 1 and 2, respectively.

The WFGD systems for Units 1 and 2 were placed in early operation in 2012 (LOS Unit 2) and 2013 (LOS Unit 1), due to the increasing sulfur content of the fuel supply. The layered NO_x control systems were placed in service in stages over several years with the systems fully in service and optimized in 2016 for both units.

3.1.2 Round II Regional Haze SIP Determination

The Round II Determination must be submitted to EPA for review by July 31, 2021. Among other requirements, the Round II Determination is required to include an assessment of the state's RPGs and LTS. To support states in

their efforts to develop the Round II Determination, in July 2016 EPA released a draft guidance document titled “*Draft Guidance on Progress Tracking Metrics, Long-term Strategies, Reasonable Progress Goals and Other Requirements for Regional Haze State Implementation Plans for the Second Implementation Period*” (“Draft EPA Guidance”).¹⁸ The Draft EPA Guidance document describes key steps states should implement when developing their RPGs and LTS for the Round II Determination. Key steps identified in the Draft EPA Guidance are listed in Table 3-2.

Table 3-2. Key Steps in Developing the Round II Determination

1.	<i>Ambient data analysis</i> – Quantify baseline, current and natural conditions and the URP that would achieve natural conditions by 2064 (40 CFR 51.308(f)(1))
2.	<i>Screening of sources</i> – Identify the pollutants and emission sources for which a full reasonable progress analysis will be completed and explain why it is appropriate to limit the full analysis to only these sources (40 CFR 51.308(f)(2))
3.	<i>Source and emission control measure analysis</i> – Identify potential emission control measures for sources selected in the screening step and develop data on the four statutory factors and visibility benefits if they will be considered (40 CFR 51.308(f)(2))
4.	<i>Decisions on the content of the LTS</i> – Consider applicable factors and decide on new emission controls for incorporation into the LTS (40 CFR 51.308(f)(2))
5.	<i>Regional scale modeling</i> – Model the emissions reductions that will result from implementation of the LTS and other enforceable measures that will reduce visibility impairment to set the RPGs for 2028 (40 CFR 51.308(f)(3))
6.	<i>Progress, degradation and glidepath checks</i> – Demonstrate that there will be an improvement on the 20 percent most impaired days. Demonstrate that there is no degradation on the 20 percent clearest days. Compare the 2028 RPG for the 20 percent most impaired days to the 2028 point on the URP line (the glidepath) and, if required, provide additional justification for the reasonableness of the RPG. Revise the LTS if additional measures are identified as necessary to make reasonable progress. (40 CFR 51.308(f)(3))
7.	<i>Additional requirements for SIPs</i> – Provide additional information necessary to ensure that other requirements of the Regional Haze rule are met.

The Draft EPA Guidance recommends that states evaluate all technically feasible emission control options for

¹⁸ See, EPA-457/P-16-001. On September 11, 2018, EPA released a “*Regional Haze Reform Roadmap*” announcing its plan to “release a series of implementation tools and guidance documents that will help focus states’ efforts and reduce and streamline the time and resources needed to meet the statutory and regulatory requirements for reducing regional haze in National Parks, wildlife refuges, and wilderness areas.” EPA stated that it plans to issue a new guidance document on Regional Haze SIP Development by Spring, 2019. Basin Electric reserves the right to update and modify this four-factor analysis, as needed, to be consistent with any new guidance issued by the agency.

stationary sources and source categories identified as having the greatest potential to impact visibility at one or more Class I area. The Draft EPA Guidance recommends several options for states to consider when evaluating potential emission reductions, including work practices, replacement and retrofit controls, existing control upgrades, fuel switching, year-round operation of controls, and operating restrictions.¹⁹

Emission control evaluations must consider the four statutory factors identified in 40 CFR 51.308(f)(2)(i) (discussed in Section 3.2). In addition, the Draft EPA Guidance notes that control technology assessment recommendations presented in the BART Guidelines continue to be relevant as recommendations for how a state should evaluate and select emission control measures for stationary sources.²⁰ Recommendations in the BART Guidelines that continue to be relevant to the Round II Determination's four factor analysis are listed in the Appendix D of the Draft EPA Guidance, and include, in general, the recommended approach for evaluating the technical feasibility, effectiveness, costs, and cost-effectiveness of available emission control measures.²¹

3.2 DESCRIPTIONS OF THE FOUR STATUTORY FACTORS

Under 40 CFR 51.308(f)(2)(i), states must consider four statutory factors when evaluating and determining emissions reduction measures from stationary sources, or groups of sources, that are necessary to make reasonable progress towards achieving natural visibility conditions. The four statutory factors are:

1. The costs of compliance;
2. The time necessary for compliance;
3. The energy and non-air quality environmental impacts of compliance; and
4. The remaining useful life of any potentially affected anthropogenic source of visibility impairment.

A brief description of each of the four statutory factors, and EPA's recommendations for evaluating each of the four factors (from the Draft EPA Guidance) is provided below.

3.2.1 Costs of Compliance

Cost estimates should be developed for each technically feasible control option. Costs include the total capital costs to engineer, design, procure, and install the control technology, and annual operations and maintenance

¹⁹ See, Draft EPA Guidance, pgs. 85-86.

²⁰ Draft EPA Guidance, pg. 85. The BART Guidelines are published at 40 CFR Part 51 Appendix Y.

²¹ Draft EPA Guidance, Appendix D, pgs. 186-196.

(O&M) costs. O&M costs include both fixed and variable O&M. Fixed O&M includes costs that are independent of control system operation and would be incurred even if the control system were shut down. Fixed O&M includes categories such as O&M labor, administrative charges, property taxes, and insurance. Variable O&M includes the cost of consumables, including reagent (e.g., lime or limestone, ammonia, urea, etc.), by-product management, water consumption, and auxiliary power requirements associated with operating the control system. For existing facilities, O&M cost estimates should represent the control option's incremental increase over current O&M costs.

Capital costs include all costs required to engineer, design, procure, and install equipment needed for the control system. The Draft EPA Guideline recommends that states adhere to the accounting principles described in Chapter 2 Section 1 of EPA's Air Pollution Control Cost Manual (the "Control Cost Manual") when calculating control system costs for a four factor analysis.²²

Section 2.3 of the Control Cost Manual (Section 1, Chapter 2) describes the cost categories generally used to calculate the total capital cost of a retrofit control technology. Cost categories include total capital investment (TCI), which is defined to "include all costs required to purchase equipment needed for the control systems (purchased equipment costs), the costs of labor and materials for installing that equipment (direct installation costs), costs for site preparation and buildings, and certain other costs (indirect installation costs). TCI also includes costs for land, working capital, and off-site facilities." Direct installation costs include costs for foundations and supports, erecting and handling the equipment, electrical work, piping, insulation, and painting. Indirect installation costs include costs such as engineering costs; construction and field expenses (i.e., cost for construction supervisory personnel, office personnel, rental of temporary offices, etc.); contractor fees (for construction and engineering firms involved in the project); start-up and performance test costs (to get the control system running and to verify that it meets performance guarantees); and contingencies.²³

The total annual cost (TAC) of a control option includes the annualized capital recovery cost plus the total annual O&M costs. The Control Cost Manual recommends using an equivalent uniform annual cash flow method to annualize the total capital investment by multiplying the total capital investment by a capital recovery factor

²² EPA Air Pollution Control Cost Manual, Sixth Edition, EPA/452/B-02-001, January 2002.

²³ EPA Air Pollution Control Cost Manual, Sixth Edition, EPA/452/B-02-001, January 2002, pg. 2-5.

(CRF).²⁴ The product of the total capital investment and CRF gives a uniform end-of-year payment necessary to repay the initial capital investment in "n" years at an interest rate of "i". The CRF is calculated using the following equation:

$$CRF = \frac{i * (1 + i)^n}{(1 + i)^n - 1}$$

Where:

i = interest rate; and

n = economic life of the emission control system

The Draft EPA Guidance suggests that states may use generic cost estimates or estimating algorithms for estimating control system costs; however, source specific estimates prepared by knowledgeable engineering professionals provide more reliable information than generic cost estimates.²⁵ Source-specific cost estimate should be well documented for purposes of public comment and EPA review.²⁶

The total annual cost of each control option (\$/yr) is divided by the total annual emissions reduction (tons/yr) to determine the control option's average cost-effectiveness on a \$/ton basis. Emissions reductions are calculated based on the difference between baseline annual emissions and post-control annual emissions. The Draft EPA Guidance generally recommends calculating baseline emissions based on projected 2028 emissions assuming source compliance with emission limits that have been adopted and are enforceable. As an alternative, baseline emissions may be based on representative data of past actual emissions, assuming there is no evident basis for using a different emissions rate. As such, the cost of compliance is based on historical baseline as well as future projected capacity factors and fuels.

3.2.2 Time Necessary for Compliance

For stationary sources, the provisions of the BART Guidelines regarding the time necessary for compliance are relevant to the Round II Determination's analyses. EPA recommends that prior experiences with the planning and installation of new emission controls is the best guide to how much time a particular source will reasonably need for compliance. However, source-specific factors should be considered when evaluating the time necessary to

²⁴ Id., at pg 2-21.

²⁵ Draft EPA Guidance, pg. 91.

²⁶ Id.

engineer, procure, and install an available and technically feasible control option. Source-specific factors that affect the time necessary to install new emission controls should be identified and documented in the four factor analysis.

3.2.3 Energy and Non-Air Quality Environmental Impacts

For stationary sources, the provisions of the BART Guidelines regarding energy impacts are relevant to Round II Determination's analyses. Energy impacts of an emission control measure are a matter of engineering design and control system operation; thus, EPA recommends that prior experience at similar sources will be informative. Energy impacts may be considered in terms of kilowatt-hours or fuels used to operate the control system. The energy impact analysis should focus on direct energy consumption at the source rather than indirect energy inputs needed to produce raw materials for the construction and operation of control equipment.

For stationary sources, the provisions of the BART Guidelines regarding non-air quality environmental impacts are relevant to the Round II Determination's analyses. Non-air quality impacts include solid or hazardous waste generation, increased water consumption, wastewater discharge, land use impacts, and impacts to threatened and endangered species or their natural habitat. Characterizing the non-air quality environmental impacts should be done on a source-specific basis. Other guidance intended for use in assessments under the National Environmental Policy Act may be relevant to this evaluation.

Even though states are not required to consider greenhouse gas (GHG) emission impacts, the Draft EPA Guidance encourages states to consider GHG impacts when developing their LTS.²⁷ As an example, some measures that would reduce emissions that contribute to visibility impairment will also reduce GHG emissions, such as measures that reduce the use of energy produced from combusting fossil fuels with relatively high GHG emissions. Conversely, control measures that require significant energy to capture visibility impairing emissions could result in increased GHG emission. Where a measure necessary to make reasonable progress towards natural visibility conditions would increase GHG emissions, Draft EPA Guidance encourages states to work to harmonize visibility and climate change objectives.²⁸

²⁷ Draft EPA Guidance, pg. 92.

²⁸ *Id.*

3.2.4 Remaining Useful Life

For stationary sources, the provisions of the BART Guidelines regarding remaining useful life are relevant to the Round II Determination's analyses. In general, the remaining useful life of the source itself will be longer than the useful life of the emission control measure under consideration unless there is an enforceable requirement for the source to cease operation sooner. Thus, the useful life of the control measure will normally be used in the four factor analysis to calculate emission reductions, amortized costs, and cost-effectiveness. However, if there is an enforceable requirement for the source to cease operation by a date before the end of what would otherwise be the useful life of the control measure under consideration, then the enforceable shutdown date should be used to calculate remaining useful life and evaluate control technology cost-effectiveness.

3.2.5 Four Factor Analysis Approach

S&L used a top-down approach to identify and evaluate the technical feasibility and effectiveness of potentially available SO₂ and NO_x control measures. S&L followed Steps 1 thru 3 of the top-down approach described in the BART Guidelines to identify all available retrofit emission control measures, eliminate technically infeasible options, and evaluate the effectiveness of the technically feasible options.²⁹ A brief description of each step is provided below.

Step 1 - Identify All Available Control Options

Available control options are those air pollution control technologies with a practical potential for application to the emission unit and the regulated pollutant under evaluation. Air pollution control technologies can include a wide variety of available methods, systems, and techniques for control of the affected pollutant, and include not only existing controls for the source category but also take into account technology transfer of controls that have been applied to similar source categories and gas streams. Technologies which have not been applied to (or permitted for) full scale operations need not be considered as available.³⁰

²⁹ See, 40 CFR Part 51 Appendix Y, Section IV.D.

³⁰ *Id.*, at IV.D.1.

In an effort to identify all potentially available emission control technologies, S&L searched a broad range of information sources including, but not necessarily limited to:

- EPA's RACT/BACT/LAER Clearinghouse (RBLC);
- EPA's New Source Review (NSR) and Clean Air Technology Center (CATC) Web sites;
- BART evaluations prepared during the initial Regional Haze planning period;
- Information from control technology vendors and engineering/environmental consultants;
- Federal and State NSR permits and BACT determinations for similar sources; and
- Technical journals, reports, newsletters and air pollution control seminars.

Step 2 - Eliminate Technically Infeasible Control Options

In Step 2, S&L evaluated the technical feasibility of the control options identified in Step 1 with respect to source-specific and unit-specific factors. Control technologies are technically feasible if either: (1) they have been installed and operated successfully for the type of source under review under similar conditions; or (2) the technology could be applied to the source under review. In order for a control option to be technically feasible, it must be "available" and "applicable" to the source under consideration. A technology is considered "available" if the source owner may obtain it through commercial channels. An available technology is "applicable" if it can reasonably be installed and operated on the source type under consideration.³¹

Control technologies that are technically infeasible (i.e., not available or not applicable to the source under consideration) are eliminated for further evaluation. A demonstration of technical infeasibility must be based on physical, chemical and engineering principals, and must show that technical difficulties would preclude the successful use of the control option on the emission unit under consideration. The economics of an option are not considered in the determination of technical feasibility/infeasibility.

Step 3 - Evaluate Technically Feasible Control Technologies for Effectiveness

Step 3 involves evaluating the control effectiveness of all the technically feasible control alternatives identified in Step 2 for the pollutant and emissions unit under review. Control effectiveness should be expressed using a metric that ensures an "apples-to-apples" comparison of emissions performance levels among options, and is generally

³¹ A more detailed description of control technology "availability" and "applicability" is provided in 40 CFR Part 51 Appendix Y, Section IV.D.2.

expressed as the rate that a pollutant is emitted after installation of the control measure. Control technology evaluations for existing sources should consider ways to improve the performance of existing control devices. Special circumstances pertinent to the specific control technology under review should be identified and taken into consideration when assessing the capability of the control alternative and determining control effectiveness.

For this evaluation, S&L assessed the technically feasible SO₂ and NO_x control options for effectiveness on LOS Unit 1, which is equipped with SOFA/LNB/SNCR/Emerson Combustion Optimizer for NO_x control and WFGD for SO₂ control. In addition, control options were assessed for technical feasibility and effectiveness for LOS Unit 2. LOS Unit 2 is equipped with SOFA/SNCR/Emerson Combustion Optimizer for NO_x control, and WFGD for SO₂ control.

4. SO₂ CONTROL EVALUATION

4.1 BASELINE SO₂ EMISSIONS

The first step in developing the four factor analysis is to establish LOS Units 1 and 2 baseline SO₂ emissions. To establish representative baseline emissions, S&L evaluated Units 1 and 2 operating data for the five year period between January 1, 2013 to September 30, 2018 to identify periods of normal operation (i.e., periods of operation when the boiler was not limited by infrequent or extraordinary operating restrictions). Based on review of fuels consumed, heat input to the boiler, boiler heat rates, power generation, and capacity factors, as well as input from Basin Electric, it was determined that the operating periods of January 1, 2013 to September 30, 2018 were representative of normal boiler operation. The Unit 2 WFGD system for SO₂ control was installed prior to the baseline period (October 2012); however, the Unit 1 WFGD system for SO₂ control was not placed in service until June 2013. Thus, the representative baseline periods for SO₂ emissions for the LOS Units are:

Table 4-1. Representative Baseline Periods for SO₂ Emissions

Pollutant	Representative Baseline Periods	
	LOS Unit 1	LOS Unit 2
SO ₂ Emissions	6/1/2013 to 9/30/2018	1/1/2013 to 9/30/2018

Baseline annual SO₂ emissions were determined based on data obtained from the Units 1 and 2 continuous emissions monitoring system (CEMS) that was reported to EPA's Clean Air Markets. The maximum 24-consecutive month annual average emission rate during the representative time period was used to establish baseline annual emissions (in terms of tons per year). Representative baseline emission factors (in terms of pounds per million British Thermal Units (lb/MMBtu)) were developed using baseline annual emissions and the respective annual heat inputs. Table 4-2 provides a summary of the LOS Units 1 and 2 baseline SO₂ emissions. Additional details are included in Appendix B.

Table 4-2: Baseline Actual SO₂ Emissions

LOS Unit	Baseline Controls	SO ₂ Emission ^(Notes 1 and 2)			Capacity Factor During Baseline Period	Current SO ₂ Control Percentage ^(Note 3)	Current Permit Limits (30-day rolling average)
		lb/hr	lb/MMBtu	tons/yr			
Unit 1	WFGD	166	0.09	697	68%	97.1%	0.15 lb/MMBtu or 95% SO ₂ removal
Unit 2	WFGD	334	0.09	1,366	69%	97.1%	0.15 lb/MMBtu or 95% SO ₂ removal

Note 1. Unit 1 SO₂ emissions based on 24-month annual average for period February 2015 to January 2017.

Note 2. Unit 2 SO₂ emissions based on 24-month annual average for period April 2016 to March 2018.

Note 3. Control percentage calculated based on the range of current annual coal SO₂ content (3.12 lb/MMBtu on Unit 1 and 3.05 lb/MMBtu on Unit 2) between 2014-2018.

Table 4-3: Projected Future Maximum SO₂ Emissions

LOS Unit	Baseline Controls	SO ₂ Emission ^(Note 1)			Capacity Factor for Future Maximum Emissions	Assumed SO ₂ Control Percentage ^(Note 1)	Current Permit Limits (30-day rolling average)
		lb/hr	lb/MMBtu	tons/yr			
Unit 1	WFGD	235	0.09	1,030	100%	97.6	0.15 lb/MMBtu or 95% SO ₂ removal
Unit 2	WFGD	454	0.09	1,989	100%	97.6	0.15 lb/MMBtu or 95% SO ₂ removal

Note 1. Baseline future maximum SO₂ emission based on a forecast future maximum coal SO₂ content of 3.73 lb/MMBtu, boiler design heat inputs of 2,622 MMBtu/hr (Unit 1) and 5,130 MMBtu/hr (Unit 2), current typical SO₂ removal of 96%, and assumes 100% capacity factor.

4.2 COAL SULFUR CONTENT

The generation of SO₂ is directly related to the sulfur content and heating value (HHV) of the fuel burned. LOS currently burns North Dakota Lignite fuel from the Freedom Mine. North Dakota lignite is characterized by a low heating value and relatively low sulfur content. Typical HHV and coal sulfur content provided by Basin Electric are listed in Table 4-4. The coal quality is based on actual annual fuel data provided by the facility between 2014 and 2018, which is a similar time period as the baseline emission rates.

Table 4-4. Baseline LOS Coal Quality (Annual)

	LOS Unit 1			LOS Unit 2		
Parameter	Minimum	Average	Maximum	Minimum	Average	Maximum
HHV (Btu/lb)	5,387	6,793	7,545	6,124	6,818	7,597
As-Received Sulfur (%)	0.56	1.06	1.90	0.61	1.04	1.78
Uncontrolled SO ₂ (lb/MMBtu)	2.08	3.12	5.04	1.99	3.05	4.67
WFGD Design (lb/MMBtu)	--	--	3.9	--	--	3.9

When reviewing the as received coal data, the standard deviation of the coal sulfur content is 0.16% for both units.

In addition, Basin Electric provided anticipated future annual average coal quality projections for the facility between 2019 and 2040. The future range in coal quality is provided in Table 4-5.

Table 4-5. Future LOS Coal Quality (Annual)

Parameter	Minimum	Average	Maximum
HHV (Btu/lb)	6,595	6,650	6,722
As-Received Sulfur (%)	0.70	0.89	1.07
Uncontrolled SO ₂ (lb/MMBtu)	2.10	2.67	3.22

The future anticipated coal quality listed in Table 4-5 are based on an annual average values and do not take into account potential deviations in the coal quality that could be seen on a short term basis. As such, the actual coal

sulfur content standard deviation (0.16%) from the current coal quality was applied, as stated above, to the maximum annual sulfur coal in Table 4-5. The results are shown in Table 4-6.

Table 4-6. Design Basis for Future Projected LOS Coal Quality (Annual)

Parameter	Unit 1	Unit 2
HHV (Btu/lb)	6,595	6,595
As-Received Sulfur (%)	1.23	1.23
Uncontrolled SO ₂ (lb/MMBtu)	3.73	3.73
Uncontrolled SO ₂ per Unit (lb/hr) ^(Note 1)	9,780	19,135
Uncontrolled SO ₂ per Unit (tons/yr) ^(Note 1)	42,837	83,811

Note 1. Uncontrolled SO₂ emissions calculated at the design heat inputs of each Unit (2,622 MMBtu/hr for Unit 1 and 5,130 MMBtu/hr for Unit 2).

Based on the evaluation above, 3.73 lb SO₂/MMBtu is used as the design basis for evaluating the SO₂ control technologies presented in this report is reasonable.

4.3 SO₂ EMISSIONS CONTROLS

4.3.1 Identify Available SO₂ Control Options

The first step in this SO₂ emissions control analysis is to identify, for the emission unit in question, all available SO₂ control options. Available control options are those air pollution control technologies and operational measures with a practical potential for application to the emission unit and the regulated pollutant under evaluation. As part of the first planning period for Regional Haze, the NDDH concluded that WFGD for SO₂ control was BART for LOS Units 1 and 2. As such, the facility is already equipped with modern high-efficiency post-combustion SO₂ control. For the Round II Determination's four factor analysis presented in this report, the NDDH requested Basin Electric to evaluate improvements or upgrades to the existing WFGD systems that could be made to reduce SO₂ emissions further. As such, S&L identified additional SO₂ control options for potential application to Unit 1 and 2 which are listed in Table 4-7.

Table 4-7. Available SO₂ Control Options

SO ₂ Control Technologies
Existing FGD Operational Improvements
Existing FGD Design Changes and Equipment Upgrades

4.3.2 Technical Feasibility of Available SO₂ Control Options

Potentially available SO₂ control options identified in Table 4-7 were evaluated for technical feasibility (i.e., availability and applicability to LOS Unit 1 and 2) based on a review of physical, chemical, and engineering principals, and an assessment of commercial availability. Options determined to be technically infeasible, or options that have no practical application to LOS Unit 1 and 2, were eliminated from further review. S&L evaluated the effectiveness of the control options determined to be technically feasible, and established an emissions performance level (i.e., control emissions rate) for each.

4.3.2.1 Operational Improvements and Equipment Upgrades on Existing WFGD

Operational and other design changes/upgrades to the existing WFGD may provide an opportunity for additional SO₂ removal and allow the units to achieve lower controlled SO₂ emissions. S&L, working with Basin Electric personnel, identified a number of potentially feasible operational changes that may be available to increase SO₂ removal efficiency with the existing equipment. Potentially available operational and design changes to the existing control system are summarized in Table 4-8. A detailed discussion of each of these options is provided in the sections below.

Table 4-8. Potential WFGD Operational Improvements and Equipment Upgrades

Existing FGD Operational Improvements
Limestone Quality
Ca:S Stoichiometric Ratio
Liquid-to-Gas (L/G) Ratio
Existing FGD Design Changes and Equipment Upgrades
Additional Spray Level
Optimized Spray Level Coverage
pH Buffer Additive

Limestone Quality

The quantity of limestone (CaCO_3) available in a wet scrubbing system compared to the amount of SO_2 entering the system is called the stoichiometric ratio (generally referenced as the Ca:S stoichiometric ratio). Reagent quality directly affects the Ca:S stoichiometric ratio in WFGD control systems. Using a high quality limestone increases the availability of reagent to support process chemistry, and reduces the limestone slurry injection rate needed for SO_2 removal. Better limestone quality allows for a potential increased SO_2 reduction efficiency with fresh limestone slurry injection rates similar to existing rates.

Limestone quality typically ranges from 85-95% for use in WFGD systems. The higher quality limestone is often used in facilities that generate commercial grade saleable gypsum; this limestone would consist of a CaCO_3 content of 95% or greater with minimal magnesium (<2.5%). For facilities that do not need to make a salable high quality WFGD byproduct, lower grade limestone quality is adequate. The quality required for disposable byproduct is typically between 85-90% CaCO_3 . Since the limestone quality is lower, it will result in higher consumption rates when compared to high quality limestone (i.e. >95%).

The LOS WFGD byproduct is currently disposed, as such using a lower quality limestone is acceptable. The facility on average receives 90% or greater CaCO_3 content, which is on the high end of quality for generating WFGD byproduct for disposal. Procuring a higher CaCO_3 content limestone would not provide any valuable improvement in WFGD performance. Thus, for these reasons, changing the limestone quality is not a technically feasible SO_2 control option for LOS, and will not be evaluated further.

Ca:S Stoichiometric Ratio

Potential operational changes may be available to increase Ca:S stoichiometry in the WFGD by increasing the fresh limestone injected into the Unit 1 or 2 WFGD system. In a WFGD system, flue gas containing SO_2 is brought into contact with limestone slurry droplets and the SO_2 is absorbed into the water droplet. Within the droplet, the SO_2 and calcium form calcium sulfite (CaSO_3) and calcium sulfate ($\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$) byproduct. As the slurry falls through the flue gas, it eventually falls into the reaction tank, where it is stored for a few minutes before being recirculated back into the flue gas stream through the recycle spray headers.

As sulfur continues to react with the available CaCO_3 , fresh limestone makeup to the system is required to maintain the necessary concentration and pH for the reactions and SO_2 removal. More frequent fresh limestone addition will ensure that there is a higher concentration of available reagent in the recycle slurry.

S&L reviewed limestone addition data provided by LOS for Units 1 and 2. At LOS Unit 1, limestone feed rate is maintained relatively close to the maximum design stoichiometry based on the inlet SO₂ concentration. Increasing the fresh limestone addition rate to operate closer to the maximum design stoichiometry could provide nominal additional SO₂ removal. Further increases to limestone consumption beyond the design rate are not recommended, due to potential harmful effects of changes of slurry pH, which can lead to scaling concerns and oxidation-reduction potential (ORP) issues. LOS has already had issues with pH control and limestone addition beyond the design rate may drive the pH too high. As such, an increase in Ca:S stoichiometry to the design is considered to be a technically feasible SO₂ control option for LOS Unit 1. This adjustment to station work practices would require a slight increase in limestone addition to achieve an 11% reduction from the baseline SO₂ hourly rate (in lb/hr).

A similar analysis was conducted on Unit 2 limestone addition rates. Similarly, there is minor improvement to achieve maximum design stoichiometry at full load based on the inlet sulfur. It is not recommended to increase the rates above design, due to the aforementioned effects of operating outside of design pH range. However, increasing stoichiometry would have to be done in conjunction with increasing the L/G ratio. The L/G, which is a measurement of the volume of liquid slurry recycled in comparison to the volumetric flow rate of gas passing through the absorber, also typically has an effect on removal efficiency. Since the limestone injection rate and the L/G ratio rely upon each other for the system to operate as design, it is difficult to predict performance improvement with increased limestone alone. As such, for LOS Unit 2, increased limestone stoichiometry will be reviewed in conjunction with increasing the L/G ratio as discussed in the next section.

Liquid-to-Gas Ratio

The L/G ratio in a WFGD is indicative of the total surface area of reagent available for the reaction with the acid gases in the flue gas, such as SO₂. L/G is an important parameter for WFGD systems to account for the design contact between the available reagent and SO₂ in the flue gas. A higher L/G ratio corresponds to more liquid volume coverage within the cross-sectional area of a WFGD vessel. As the L/G ratio increases, there is additional contact of the flue gas with the limestone slurry as it passes through the absorber vessel, which can increase the removal efficiency.

L/G ratio can be improved by increasing the liquid flowrate through each recycle spray header. WFGD spray headers are designed with a spray volume coverage required by the performance of the system. As inlet conditions vary over time, the spray flow can be adjusted to maintain the necessary spray for design performance. Additionally, adjustments in unit load will cause the L/G ratio to vary; however if the system is setup at a constant

recycle slurry flow rate, the L/G ratio will be higher at lower loads, which provides higher SO₂ removal efficiencies.

S&L estimated recycle slurry flow rates based on pump operating data provided by LOS for Units 1 and 2. Based on the data provided, the Unit 1 pumps operate with three of the four spray levels always in service. Current industry practice for WFGD systems are such that the system is designed with a spare recycle pump and spray level in order to maintain SO₂ removal while performing maintenance activities on the recycle pumps. Furthermore, the recycle flow rate data suggest that all Unit 1 operating pumps are working at their maximum capacity at all times. This was confirmed by LOS operating personnel that explained that the recycle pumps are manually operated and not adjusted for operating load or SO₂ loading. This suggests there is no potential for increased L/G ratio without major modifications to the spray headers. For these reasons, changes to L/G ratio is not considered to be a technically feasible SO₂ reduction option for LOS Unit 1, and will not be evaluated further.

As mentioned in the previous section, Unit 2 is not operating at its maximum design L/G ratio. The design of the Unit 2 WFGD is based on four of five recycle pumps operating at maximum flow at full load, to satisfy the design operating profile; however, the facility has only been operating three at a time, due to lower inlet sulfur loading than design (3.9 lb/MMBtu) and is still maintaining SO₂ emissions below the permitted limit. Fuel forecasts suggest that the inlet sulfur loading could increase to 3.73 lb/MMBtu on a short term basis, within the next 5-10 years, from the baseline SO₂ fuel composition of 3.05 lb/MMBtu for Unit 2. As the facility starts to burn higher sulfur coal in comparison to the recent historical quality, the site personnel can manually place the fourth pump in service.

However, based on review of data provided by LOS, the flow rate of the pumps that are in operation is less than design, which is mainly due to the rigorous required maintenance to keep them at full efficiency and design flow rate. If the pumps are increased to maximum design capacity and the limestone is increased to the appropriate ratio (as referenced in the previous section), the Unit 2 WFGD would be expected to achieve a nominal reduction in SO₂ emissions at full load. For these reasons, operating changes resulting in an increase in Ca:S stoichiometry in conjunction with an increase in L/G is considered to be a technically feasible SO₂ control option for LOS Unit 2, and will be evaluated further. It is expected that the adjustment to station work practices may achieve a 15% reduction from the baseline SO₂ hourly rate (in lb/hr).

Additional Spray Level

Another method to increase L/G ratio in a WFGD system is to increase the amount of spray levels. As mentioned previously, Units 1 and 2 are designed with a spare spray level to account for a certain level of redundancy for maintenance purposes. If increased L/G ratio cannot be obtained by increasing the throughput of slurry through the existing spray headers, an additional recycle pump and spray header may be added. An additional spray level would increase the L/G ratio by 33% on Unit 1 and 20% on Unit 2.

The original equipment manufacturer (OEM) provided correction curves that suggest an additional 1% removal efficiency could be achieved with all pumps and spray levels in service at both LOS units. As such, it is expected that installing an additional spray level would improve LOS Unit 1 and 2 performance. However, S&L reviewed the absorber drawings for each unit and concludes there is no room for an additional slurry spray level. Due to the location of the mist eliminators which are directly above the highest spray level and the inlet flue gas duct located directly below the first spray level, there is no room to install another spray level unless the top of the absorber is extended to make room for another spray level. All of the internals in this section would need to be restructured including the outlet cone ductwork to the chimney. For these reasons, an additional spray header is not considered to be a technically feasible SO₂ control option for LOS Unit 1 or 2, and will not be evaluated further.

Optimized Spray Level Coverage

Another option for improving the design of the WFGD system is by ensuring there is full coverage of the slurry spray through the cross-sectional area of the absorber. Improving distribution of the slurry as well as spray nozzle design can reduce localized flue gas slippage as well as increase L/G. Improvements to spray design can provide better pattern of coverage, finer droplet size and more even coverage.

S&L consulted the WFGD OEM to determine if there have been any developments in spray header design since the LOS WFGD's were installed. The OEM concluded that the LOS WFGD systems were originally designed with state of the art spray coverage and up/down nozzle patterns, which is consistent with the most modern WFGD systems. As such no additional improvements could be made to the spray nozzle design to improve the WFGD efficiency. For these reasons, optimizing the spray nozzle design is not considered to be a technically feasible SO₂ control option for LOS Unit 1 or 2, and will not be evaluated further.

pH Buffer Additive

As discussed previously, there is a limit to the amount of fresh limestone makeup that can be added to the WFGD. WFGD systems require a delicate balance of pH to allow for proper reaction kinetics and limit the scaling potential within the system. As SO₂ from the flue gas dissolves in the slurry, the water becomes acidic. Limestone is added, which neutralizes the slurry. However, limestone does not dissolve readily, thus making it difficult to neutralize the SO₂ as it enters. Since the solubility of limestone is minimal, there is only a small amount of dissolved limestone on the surface of the slurry droplet to react with SO₂.

Additives have been developed for use in WFGD systems to improve the ability for limestone to neutralize and react with SO₂. Thus use of additives such as dibasic acid (DBA) increase the removal efficiency in WFGD systems. DBA is a mixture of dicarboxylic acids, or carbon chains with carboxylic acids. The DBA quickly combines with free hydrogen ions at the gas-liquid interface, which hinders the slurry from dropping in pH. The increased alkalinity raises the solubility of SO₂ within the limestone slurry, thus expanding the efficiency of the absorber column.

The use of DBA in conjunction with increasing fresh limestone injection rates is expected to provide the WFGD with an additional 1% SO₂ removal efficiency. This performance could be obtained for the expected fuel sulfur content up to 3.73 lb/MMBtu. The facility is currently equipped with two common limestone ball mills, one operating and one spare, and a forwarding system with four slurry pumps. Based on the maximum future fuel sulfur content, the ball mills and slurry forwarding systems have sufficient capacity to provide the additional limestone required for Units 1 and 2 while still maintaining complete redundancy. Additional equipment for the DBA addition system would require a small tank and pump to add to the slurry holding tank. As such, DBA and increased limestone makeup is determined to be a technically feasible option for providing additional SO₂ removal efficiency on LOS Units 1 and 2.

4.3.2.2 Technical Feasibility Summary

Table 4-9 and Table 4-10 summarize the results of the feasibility evaluation of available control options for LOS Units 1 and 2.

Table 4-9. Technically Feasible SO₂ Control Options for LOS Unit 1

SO ₂ Control Option	Technically Feasible (Yes/No)	Control Percentage (Note 1)	Technical Feasibility Summary
Existing FGD Operational Improvements:			
Limestone Quality	No	0%	Changing limestone quality in the existing WFGD control system is not a technically feasible operational change for LOS Unit 1.
Ca:S Stoichiometric Ratio	Yes	97.4%	Increasing the Ca:S stoichiometric ratio by increasing the quantity of fresh limestone to the system is considered a technically feasible option for LOS Unit 1.
L/G Ratio	No	0%	Increasing the slurry recirculation rate (L/G) on the existing WFGD control system is not a technically feasible option for LOS Unit 1.
Existing FGD Design Changes and Equipment Upgrades:			
Additional Spray Level	No	0%	Adding a spray level to the existing WFGD control system is not a technically feasible upgrade for LOS Unit 1.
Optimized Spray Level Coverage	No	0%	Optimizing the slurry spray level coverage on the existing WFGD control system is not a technically feasible option for LOS Unit 1.
pH Buffer Additive	Yes	98.2%	Incorporating pH buffer to the limestone slurry and increasing limestone addition rate is a technically feasible option for LOS Unit 1.

Note 1. Control percentage calculated using the baseline SO₂ coal quality of 3.12 lb/MMBtu and the achievable SO₂ emission rate for each technically feasible control option.

Table 4-10. Technically Feasible SO₂ Control Options for LOS Unit 2

SO ₂ Control Option	Technically Feasible (Yes/No)	Control Percentage (Note 1)	Technical Feasibility Summary
Existing FGD Operational Improvements:			
Limestone Quality	No	0%	Changing limestone quality in the existing WFGD control system is not a technically feasible operational change for LOS Unit 2.
Ca:S Stoichiometric Ratio	Yes	97.5%	Increasing the Ca:S stoichiometric ratio by increasing the quantity of fresh limestone to the system is considered a technically feasible option for LOS Unit 2, but should be done in conjunction with increasing the slurry recirculation rate (L/G).
L/G Ratio	Yes		
Existing FGD Design Changes and Equipment Upgrades:			
Additional Spray Level	No	0%	Adding a spray level to the existing WFGD control system is not a technically feasible upgrade for LOS Unit 2.
Optimized Spray Level Coverage	No	0%	Optimizing the slurry spray level coverage on the existing WFGD control system is not a technically feasible option for LOS Unit 2.
pH Buffer Additive	Yes	98.4%	Incorporating pH buffer to the limestone slurry and increasing limestone addition rate is a technically feasible option for LOS Unit 2.

Note 1. Control percentage calculated using the baseline SO₂ coal quality of 3.05 lb/MMBtu and the achievable SO₂ emission rate for each technically feasible control option.

4.3.3 Evaluate Technically Feasible SO₂ Control Options for Effectiveness

The technically feasible SO₂ control technologies are listed in Table 4-11 and Table 4-12 in descending order of control efficiency. They also provide control option-specific SO₂ emission rates in terms of lb/MMBtu. Emission rates shown represent average emission rates that the control options would be expected to achieve during normal operations on a long-term averaging basis.

**Table 4-11. Evaluate Technically Feasible SO₂ Control Options by Effectiveness for LOS Unit 1
(Baseline Average Emissions)**

Alt. No.	Control Technology	SO ₂ Emission Rate ^(Note 1) lb/MMBtu	% Reduction from Baseline SO ₂ Coal Quality ^(Note 2)	SO ₂ Emission Rate ^(Note 1) lb/hr	SO ₂ Emission Rate ^(Note 1) tons/yr
B	FGD Upgrades – pH Buffer Addition	0.055	98.2	102	427
A	FGD Operational Improvements – Ca:S Stoichiometry	0.08	97.4	148	622
--	Baseline (existing WFGD)	0.09	97.1	166	697
--	Permit Limit	0.15 (30-day)	95		

Note 1: Emission rates shown in Table 4-11 represent average emission rates that the control options would be expected to achieve on an on-going long-term basis under normal operating conditions for LOS Unit 1. Emission rates are provided for comparative purposes, and should not be construed to represent proposed permit limits. Corresponding permit limits must be evaluated on a control system-specific basis.

Note 2: Baseline SO₂ coal quality is 3.12 lb/MMBtu. See Section 4.2 for additional details on coal sulfur.

**Table 4-12. Evaluate Technically Feasible SO₂ Control Options by Effectiveness for LOS Unit 2
(Baseline Average Emissions)**

Alt. No.	Control Technology	SO ₂ Emission Rate ^(Note 1) lb/MMBtu	% Reduction from Baseline SO ₂ Coal Quality ^(Note 2)	SO ₂ Emission Rate ^(Note 1) lb/hr	SO ₂ Emission Rate ^(Note 1) tons/yr
B	FGD Upgrades – pH Buffer Addition	0.05	98.4	189	772
A	FGD Operational Improvements – Ca:S Stoichiometry and L/G Ratio	0.075	97.6	283	1,158
--	Baseline (existing WFGD)	0.09	97.2	334	1,366
--	Permit Limit	0.15 (30-day)	95		

Note 1: Emission rates shown in Table 4-12 represent average emission rates that the control options would be expected to achieve on an on-going long-term basis under normal operating conditions for LOS Unit 2. Emission rates are provided for comparative purposes, and should not be construed to represent proposed permit limits. Corresponding permit limits must be evaluated on a control system-specific basis.

Note 2: Baseline SO₂ coal quality is 3.05 lb/MMBtu. See Section 4.2 for additional details on coal sulfur.

Table 4-13 and Table 4-14 provide control option-specific SO₂ emission rates in terms of lb/MMBtu based on the projected future maximum emission rates. Emission rates shown represent the projected future maximum emission rates that the control options would be expected to achieve during normal operations.

**Table 4-13. Evaluate Technically Feasible SO₂ Control Options by Effectiveness for LOS Unit 1
(Projected Future Maximum Emissions)**

4.4 COSTS OF COMPLIANCE (STATUTORY FACTOR ONE)

The economic analysis performed as part of the four factor analysis examines the cost-effectiveness of each technically feasible control technology, on a dollar per ton of pollutant removed basis. Annual emissions,

calculated for a particular control device, are subtracted from baseline annual emissions to calculate tons of pollutant controlled per year. For units with existing controls, the base case represents existing baseline actual emissions. Annual costs for each control option are calculated relative to the base case by adding annual O&M costs to the annualized cost of capital and, if applicable, lost revenue due to extended outage required for installation of control equipment. Capital costs and lost revenues were annualized using a capital recovery factor based on an annual interest rate of 5.25% and equipment life of 20 years.³² Cost effectiveness (\$/ton) of a particular control option is simply the annual cost (\$/yr) divided by the annual reduction in annual emissions (tons/yr). In addition to cost-effectiveness relative to the base case, the incremental cost-effectiveness to go from one level of control to the next, more stringent, level of control may also be calculated to evaluate the incremental cost effectiveness of the more stringent control.

Capital and O&M cost estimates were developed for each of the technically feasible SO₂ control options. The LOS Units 1 and 2 cost estimates are conceptual in nature; thus, S&L did not procure equipment quotes specifically for the Units 1 and 2 control system upgrades. Rather, equipment costs are based on conceptual designs developed for the retrofit control systems, preliminary equipment sizing developed for the major pieces of equipment (based on Units 1 and 2-specific design parameters, including typical fuel characteristics, full load heat input, and flue gas temperatures and flow rates), and recent pricing for similar equipment. S&L would characterize the cost estimates for the LOS Units 1 and 2 retrofit technologies as “concept screening” cost estimates generally based on parametric models, judgment, or analogy.

Control technology equipment costs for the retrofit options were developed by scaling cost estimates prepared by S&L for other similar projects. Major equipment costs were developed based on equipment costs recently developed for similar projects, and include the equipment, material, labor, and all other direct costs needed to retrofit the units with the control technology. Sub-accounts for the capital cost estimates (e.g., mobilization and demobilization, consumables, contractor general and administrative (G&A) expense, freight on materials, etc.) were developed by applying ratios from detailed cost estimates that were prepared for projects with similar scopes.

³² The assumed 20-year equipment life is consistent with the control system equipment life used by NDDH in its evaluation of NO_x and SO₂ control technologies for BART-eligible sources. (see, e.g., ND Regional Haze Final SIP, Appendix C.1, “BART Determination Study for Leland Olds Station Units 1 & 2, Basin Electric Power Cooperative, August 2006, pgs. 64 (NO_x controls) and 158 (SO₂ controls). See also, ND Regional Haze Final SIP, Appendix C4, “NO_x Best Available Control Technology Study for Milton R. Young Station Unit 1, Minnkota Power Cooperative, Inc., October 2006, pg. 3-22).

Fixed O&M costs include operating labor, maintenance labor, maintenance material, and administrative labor. Variable O&M costs include the cost of consumables, including reagent, water consumption, and auxiliary power requirements.³³ Auxiliary power requirements reflect the additional power requirements associated with the operation of the new control technology (compared to the existing technology). All O&M costs reflect the incremental increase in O&M costs compared to the costs incurred to operate the existing WFGD systems.

In addition to the cost effectiveness relative to the base case, the incremental cost-effectiveness to go from one level of control to the next more stringent level of control will also be calculated to evaluate the cost effectiveness of the more stringent control.

4.4.1 SO₂ Average Annual Economic Evaluation

Table 4-15 and Table 4-16 present the capital costs and annual operating costs associated with installing and operating each technically feasible SO₂ control system for LOS Unit 1 and 2. They also show the average annual and incremental cost effectiveness for each control system. Additional cost details are provided in Appendix C.

Table 4-15. SO₂ Control Cost Summary (Average Annual)

LOS Unit No.	Alt. No.	SO ₂ Control Option	Total Capital Investment \$	Annual Capital Recovery Cost \$/yr	Annual Operating Cost \$/yr	Total Annual Cost \$/yr
Unit 1	B	FGD Upgrades – pH Buffer Addition	\$8,266,000	\$677,000	\$4,156,000	\$4,833,000
	A	FGD Operational Improvements – Ca:S Stoichiometry	\$0	\$0	\$752,000	\$752,000
Unit 2	B	FGD Upgrades – pH Buffer Addition	\$11,560,000	\$947,000	\$7,340,000	\$8,287,000
	A	FGD Operational Improvements – Ca:S Stoichiometry and L/G Ratio	\$0	\$0	\$1,439,000	\$1,439,000

Note 1. Annual operating costs based on baseline SO₂ coal quality (3.12 and 3.05 lb/MMBtu for Units 1 and 2, respectively) and capacity factor during baseline SO₂ period for each LOS Unit.

³³ Variable O&M costs are based on the future coal SO₂ of 3.66 lb/MMBtu

Table 4-16. SO₂ Emissions Control System Cost Effectiveness (Average Annual)

LOS Unit No.	Alt. No.	SO ₂ Control Option	Total Annual Cost \$	Expected Emission Reduction tons SO ₂ /yr	Average Annual Cost-Effectiveness \$/ton SO ₂ removed	Incremental Annual Cost-Effectiveness (Note 1) \$/ton SO ₂ removed
Unit 1	B	FGD Upgrades – pH Buffer Addition	\$4,833,000	269	\$17,948	\$21,013
	A	FGD Operational Improvements – Ca:S Stoichiometry	\$752,000	75	\$10,021	
Unit 2	B	FGD Upgrades – pH Buffer Addition	\$8,287,000	594	\$13,946	\$17,748
	A	FGD Operational Improvements – Ca:S Stoichiometry and L/G Ratio	\$1,439,000	208	\$6,906	

Note 1. Incremental cost-effectiveness represents the incremental increase in annual costs (\$/yr) divided by the incremental increase in annual SO₂ emissions reductions (tons/yr) between a control option and the next most effective option.

Note 2. Expected emission reductions and average annual cost-effectiveness based on baseline SO₂ coal quality (3.12 and 3.05 lb/MMBtu for Units 1 and 2, respectively) and capacity factor during baseline SO₂ period for each LOS Unit.

Table 4-16 indicates that the average annual cost effectiveness of the technically feasible SO₂ control options for Unit 1 range from \$10,021 per ton (FGD operational improvements – Increase Ca:S stoichiometric ratio) to \$17,948 per ton (FGD upgrades – pH buffer addition) SO₂ removed; and for Unit 2 ranges from \$6,906 per ton to \$13,946 per ton of SO₂ removed.

Operational improvements to the Unit 1 existing WFGD system by improving Ca:S stoichiometric ratio is expected to achieve approximately 11% SO₂ reduction from the baseline for a cost effectiveness of approximately \$10,000 per ton. This is due to the expected operating costs of increased limestone consumption in comparison with the limited additional SO₂ removal on an annual basis. Upgrading the existing WFGD system with pH buffer addition on Unit 1 is expected to achieve approximately 39% SO₂ reduction from baseline emission rates. The cost effectiveness of this option is approximately \$18,000 per ton. The cost is mainly driven by pH buffer additive costs with limited annual SO₂ emission reduction. Compared to the operational improvements alone, the incremental cost effectiveness of the upgrades is approximately \$21,000 per ton for Unit 1.

Operational improvements to the Unit 2 existing WFGD system by improving Ca:S stoichiometric ratio is expected to achieve approximately 15% SO₂ reduction from the baseline at a cost effectiveness of approximately \$7,000 per ton. This is due to the expected operating costs of increased limestone consumption in comparison with the limited additional SO₂ removal on an annual basis. Upgrading the existing WFGD system with pH buffer addition on Unit 2 is expected to achieve approximately 44% SO₂ reduction from baseline emission rates. The cost effectiveness of this option is approximately \$14,000 per ton. The cost is mainly driven by pH buffer additive costs with limited annual SO₂ emission reduction. Compared to the operational improvements alone, the incremental cost effectiveness of the upgrades is approximately \$18,000 per ton for Unit 2.

4.4.2 SO₂ Potential-to-Emit Annual Economic Evaluation

Table 4-17 presents the capital costs and annual operating costs associated with building and operating each control system; annual operating costs are based on the units operating at 100% capacity factor and future coal quality considering potential variability.

Table 4-17. SO₂ Control Cost Summary (Projected Future Maximum)

LOS Unit No.	Alt. No.	SO ₂ Control Option	Total Capital Investment \$	Annual Capital Recovery Cost \$/yr	Annual Operating Cost \$/yr	Total Annual Cost \$/yr
Unit 1	B	FGD Upgrades – pH Buffer Addition	\$8,266,000	\$677,000	\$6,865,000	\$7,542,000
	A	FGD Operational Improvements – Ca:S Stoichiometry	\$0	\$0	\$2,019,000	\$2,019,000
Unit 2	B	FGD Upgrades – pH Buffer Addition	\$11,560,000	\$947,000	\$12,429,000	\$13,376,000
	A	FGD Operational Improvements – Ca:S Stoichiometry and L/G Ratio	\$0	\$0	\$4,078,000	\$4,078,000

Note 1. Annual operating costs based on projected future maximum SO₂ coal quality (3.73 lb/MMBtu) and 100% capacity factor for each LOS Unit.

Table 4-18 shows the average annual and incremental cost effectiveness for each control system with emissions reductions and cost effectiveness values based on 100% capacity factors and projected future maximum emission rates. Additional cost details are provided in Appendix C.

**Table 4-18. SO₂ Emissions Control System Cost Effectiveness
(Projected Future Maximum)**

LOS Unit No.	Alt. No.	SO ₂ Control Option	Total Annual Cost \$	Expected Emission Reduction tons SO ₂ /yr	Average Annual Cost-Effectiveness \$/ton SO ₂ removed	Incremental Annual Cost-Effectiveness (Note 1) \$/ton SO ₂ removed
Unit 1	B	FGD Upgrades – pH Buffer Addition	\$7,542,000	398	\$18,948	\$19,237
	A	FGD Operational Improvements – Ca:S Stoichiometry	\$2,019,000	111	\$18,200	
Unit 2	B	FGD Upgrades – pH Buffer Addition	\$13,376,000	865	\$15,462	\$16,552
	A	FGD Operational Improvements – Ca:S Stoichiometry and L/G Ratio	\$4,078,000	303	\$13,444	

Note 1. Incremental cost-effectiveness represents the incremental increase in annual costs (\$/yr) divided by the incremental increase in annual SO₂ emissions reductions (tons/yr) between a control option and the next most effective option.

Note 2. Expected emission reductions and average annual cost-effectiveness based on baseline SO₂ coal quality (3.73 lb/MMBtu) and 100% capacity factor for each LOS Unit.

Table 4-18 indicates that the average annual cost effectiveness of the technically feasible SO₂ control options for Unit 1 range from \$18,200 per ton (FGD operational improvements – Increase Ca:S stoichiometric ratio) to \$18,948 per ton (FGD upgrades – pH buffer addition) SO₂ removed; and for Unit 2 ranges from \$13,444 per ton to \$15,462 per ton of SO₂ removed.

Operational improvements to the Unit 1 existing WFGD system by improving Ca:S stoichiometric ratio is expected to achieve approximately 11% SO₂ reduction from the baseline for a cost effectiveness of approximately \$18,000 per ton. This is due to the expected operating costs of increased limestone consumption in comparison with the limited additional SO₂ removal on an annual basis. Upgrading the existing WFGD system with pH buffer addition on Unit 1 is expected to achieve approximately 39% SO₂ reduction from baseline emission rates. The cost effectiveness of this option is approximately \$19,000 per ton. The cost is mainly driven by pH buffer additive costs with limited annual SO₂ emission reduction. Compared to the operational improvements alone, the incremental cost effectiveness of the upgrades is approximately \$19,000 per ton for Unit 1.

Operational improvements to the Unit 2 existing WFGD system by improving Ca:S stoichiometric ratio is expected to achieve approximately 15% SO₂ reduction from the baseline at a cost effectiveness of approximately \$13,000 per ton. This is due to the expected operating costs of increased limestone consumption in comparison with the limited additional SO₂ removal on an annual basis. Upgrading the existing WFGD system with pH buffer addition on Unit 2 is expected to achieve approximately 44% SO₂ reduction from baseline emission rates. The cost effectiveness of this option is approximately \$15,000 per ton. The cost is mainly driven by pH buffer additive costs with limited annual SO₂ emission reduction. Compared to the operational improvements alone, the incremental cost effectiveness of the upgrades is approximately \$16,000 per ton for Unit 2.

5. NO_x CONTROL EVALUATION

5.1 BASELINE NO_x EMISSIONS

The first step in developing the four factor analysis is to establish LOS Units 1 and 2 baseline NO_x emissions. To establish representative baseline emissions, S&L evaluated Units 1 and 2 operating data for the five year period between January 1, 2013 to September 30, 2018 to identify periods of normal operation (i.e., periods of operation when the boiler was not limited by infrequent or extraordinary operating restrictions). Based on review of fuels consumed, heat input to the boiler, boiler heat rates, power generation, and capacity factors, as well as input from Basin Electric, it was determined that the operating periods of January 1, 2013 to September 30, 2018 were representative of normal boiler operation. However, during the baseline operating period, the BART compliance emission control technologies were installed. SNCR systems for NO_x control were placed into service and considered optimized in September 2017 for Unit 1 and in April 2017 for Unit 2. Thus, the representative baseline periods for NO_x emissions for the LOS Units are:

Table 5-1. Representative Baseline Periods for NO_x Emissions

Pollutant	Representative Baseline Periods	
	LOS Unit 1	LOS Unit 2
NO _x Emissions	9/1/2017 to 9/30/2018	4/1/2017 to 9/30/2018

Baseline annual NO_x emissions were determined based on data obtained from the Units 1 and 2 CEMS that was reported to EPA's Clean Air Markets. The maximum 12-consecutive month annual average emission rate during the representative time period was used to establish baseline annual emissions (in terms of tons/yr). A 12-month average was used rather than 24-month averaging timeframe (as used in the SO₂ evaluation) due to the recent NO_x control optimization technology implementation. Representative baseline emission factors (in terms of pounds per million British Thermal Units (lb/MMBtu)) were developed using baseline annual emissions and the respective annual heat inputs. Table 4-2 provides a summary of the LOS Units 1 and 2 baseline NO_x emissions. Additional details are included in Appendix B.

Table 5-2: Baseline Actual NO_x Emissions

LOS Unit	Baseline Controls	NO _x Emission ^(Note 1)			Capacity Factor During Baseline Period	Current Permit Limits
		lb/hr	lb/MMBtu	tons/yr		
Unit 1	LNB / SOFA / SNCR	255	0.15	905	51%	0.19 lb/MMBtu (30-day average)
Unit 2	SOFA / SNCR	1,099	0.30	4,530	68%	0.35 lb/MMBtu (30-day average)

Note 1. Unit 1 annual NO_x emissions for period July 2017 to June 2018.

Note 2. Unit 2 annual NO_x emissions for period April 2017 to March 2018.

Table 5-3: Baseline Projected Future Maximum NO_x Emissions

LOS Unit	Baseline Controls	NO _x Emission ^(Note 1)			Capacity Factor for Future Maximum Emissions	Current Permit Limits
		lb/hr	lb/MMBtu	tons/yr		
Unit 1	LNB / SOFA / SNCR	406	0.15	1,779	100%	0.19 lb/MMBtu (30-day average)
Unit 2	SOFA / SNCR	1,528	0.30	6,692	100%	0.35 lb/MMBtu (30-day average)

Note 1. Baseline future maximum NO_x emission based on boiler design heat input of 2,622 MMBtu/hr (Unit 1) and 5,130 MMBtu/hr (Unit 2) and assumes 100% capacity factor.

5.2 NO_x EMISSIONS CONTROLS

5.2.1 Identify Available NO_x Control Options

Based on a review of available NO_x control technologies installed on existing opposed-fired pulverized coal boilers and cyclone boilers designed to fire lignite coal, NO_x control techniques can be divided into pre-combustion strategies and post-combustion controls. NO_x control options identified for potential application to LOS Unit 1 and 2 are listed in Table 5-4.

Table 5-4. Available NO_x Control Options

NO _x Control Technologies
Selective Catalytic Reduction - High Dust, Low Dust or Tail End Configuration (TE-SCR)
Optimized Selective Non-Catalytic Reduction (SNCR)
Rich Reagent Injection (RRI)
Optimized SCR + RRI
Gas Reburn
Innovative Technologies (i.e. NO _x Star, Water Injection, LoTOX, PerNO _x ide, Water Injection)

5.2.2 Technical Feasibility of Available NO_x Control Options

Potentially available NO_x control options identified in Table 5-4 were evaluated for technical feasibility (i.e. availability and applicability to LOS Unit 1 and 2) based on a review of physical, chemical, and engineering principals, and an assessment of commercial availability. Options deemed to be technically infeasible, or options that have no practical application to LOS Unit 1 and 2, were eliminated from further review. S&L evaluated the effectiveness of the control options determined to be technically feasible, and established an emission performance level (i.e., controlled emission rate) for each.

5.2.2.1 Selective Catalytic Reduction

SCR is a process by which ammonia (NH₃) reacts with nitric oxide (NO) and nitrogen dioxide (NO₂), collectively NO_x, in the presence of a catalyst to reduce the NO_x to nitrogen (N₂) and water. SCR technology has been applied

to NO_x-bearing flue gases generated from power generating facilities burning various types of coal, including bituminous, subbituminous, and Texas lignite). The principal reactions resulting in NO_x reduction are:

Because these reactions proceed slowly at typical boiler exit gas temperatures of a coal-fired steam EGU, a catalyst is used to increase the reaction rate between NO_x and ammonia. Depending on the specific constituents in the flue gas, a typical temperature range of 550°F to 780°F is necessary to achieve normal performance of the catalyst. For the typical coal-fired boiler, optimal performance will be in the range of approximately 650°F to 750°F.

In general, there are three candidate SCR configurations that can be employed on coal-fired steam EGUs. The SCR configuration designations generally describe the location of the SCR reaction vessel in relation to other post-combustion air quality control systems. Candidate SCR configurations include:

- High-dust configuration
- Low-dust configuration
- Tail-end configuration

Each of these configurations is described below as they may be applied at LOS Unit 1 and 2.

High-Dust Configuration

In a high-dust configuration, the SCR reactor is located in the flue gas stream between the economizer outlet and the air heater inlet. This configuration locates the SCR within the inherently optimal temperature range environment for NO_x reduction (i.e., 650°F to 750°F); however, flue gas characteristics at the economizer outlet can also have detrimental effects on the SCR catalyst. As an example, the high-dust SCR configuration exposes the SCR catalyst to high levels of fly ash loading. High levels of fly ash can result in significant erosion of the catalyst, resulting in more frequent cleaning cycles and catalyst replacement. A second major concern with the high-dust configuration at LOS Units 1 and 2 is the presence of high levels of sodium (both in the vapor-phase and as submicron aerosols) in the North Dakota lignite-derived flue gas. Sodium is a known SCR catalyst poison, and also affects the adhesive and cohesive characteristics of the fly ash, which in turn, would have an adverse effect on the SCR catalyst and reactor vessel.

SCR catalyst deactivation occurs through two primary mechanisms: physical deactivation and chemical poisoning. Physical deactivation is caused by either exposure of the catalyst to excessive temperatures (thermal deactivation)

or masking of the catalyst due to entrainment of particulate from the flue gas stream (fouling). Chemical deactivation is caused by either an irreversible reaction of the catalyst with a contaminant in the gas stream (poisoning) or a reversible absorption of a contaminant on the surface of the catalyst (inhibition). Loss of catalyst activity through thermal degradation or poisoning is permanent, and reactivity can only be restored by replacing the catalyst.

In a North Dakota lignite application, SCR catalyst poisoning is expected to result from the presence of trace elements and strong alkaline substances in flue gas, including sodium (Na), potassium (K), calcium (Ca), and magnesium (Mg). Alkaline metals can chemically attach to active catalyst pore sites and cause deactivation. Sodium and potassium are of prime concern especially in their water-soluble forms, which are more mobile and can penetrate into the catalyst pores. Earth metals, especially calcium, can react with sulfur trioxide (SO₃) absorbed within the catalyst to form CaSO₄ and blind the catalyst.

North Dakota lignite contains relatively high levels of organically associated alkali and alkaline-earth elements, including Na, K, Ca, and Mg. Sodium levels in North Dakota lignite are typically 5 to 20 times higher than sodium levels in bituminous and subbituminous coals, and sodium compounds can represent between 5% and 11% of the ash generated from firing North Dakota lignite. These sodium levels, occurring in both the vapor phase and particulate phase, along with relatively high levels of potassium and calcium, significantly increase the potential for catalyst deactivation, plugging, and erosion. Based on the ash chemistry, a conventional high dust SCR arrangement would likely experience unacceptable catalyst deactivation rates.

As noted in Section 3.1.1.2, during the first Regional Haze planning period, NDDH prepared a comprehensive technical feasibility assessment of high dust SCR on lignite-fired boilers (North Dakota Regional Haze SIP, Appendix B-5).³⁴ The NDDH concluded, based on the unique characteristics of North Dakota lignite-derived flue gas, that the high-dust SCR configuration was not a technically feasible or commercially available NO_x control option for North Dakota lignite-fired boilers such as LOS Unit 1 and 2.³⁵ This determination was consistent with

³⁴ See, North Dakota State Implementation Plan for Regional Haze, February 24, 2010, Appendix B.5, Best Available Retrofit Technology – Selective Catalytic Reduction Technical Feasibility Analysis for North Dakota Lignite, July 2009.

³⁵ See, North Dakota State Implementation Plan for Regional Haze, February 24, 2010, Appendix B.9, Best Available Retrofit Technology – Selective Catalytic Reduction Technical Feasibility Analysis for North Dakota Lignite, July 2009, pg. 19.

the NDDH's NO_x BACT determination for MRYS Units 1 & 2.³⁶ Reasons upon which NDDH based its conclusion that high-dust SCR was not a technically feasible option for North Dakota lignite-fired boilers included, but were not limit to:³⁷

- 1) North Dakota lignite³⁸ has a higher organic matter content and contains a higher proportion of alkali metal constituents, especially sodium, than subbituminous coal. Approximately 75% of the total sodium in lignite is associated with the organic fraction of the lignite. During combustion, organic and water-soluble sodium vaporizes; consequently, combustion of the coal leads to higher flue-gas concentrations of alkali metals in vapor form.
- 2) The unburned or partially burned organic fraction of North Dakota lignite contains more sodium than other coals. Sodium can react with silicate particles causing a "stickiness" quality to the flue gas ash, resulting in increased ash deposition on heat transfer surfaces. Larger particles can fracture from heat-transfer surfaces (a.k.a. popcorn ash) and enter the flue gas stream. Consequently, deposition on surfaces of catalytic reactors occurs and rates of deposition are higher.
- 3) NO_x reduction occurs on the flat surfaces of a catalyst and in pores within the flat surfaces. The pores are open to the flue gas passing through the catalyst reactor. Condensed vapors, alkali sulfates and alkaline-earth oxides and silicates are minute particles (less than 1 microns), which enter pores of the catalyst (a.k.a. plugging) and prevent catalytic reaction with NO_x. Residual alkali vapors (Na, K, and Ca) displace hydrogen on fresh catalyst, which prevents catalytic reaction with NO_x (a.k.a. poisoning) and reacts with sulfate to cause blinding of catalyst surfaces. Pore condensation of sodium also causes catalyst deactivation, which is a major deactivation mechanism. The rate of catalyst deactivation depends on the concentration and form of alkali in the flue gas; higher Na and K accelerate catalyst poisoning, blinding and plugging.
- 4) During the development of the initial planning period SIP, NDDH found that there were no SCR systems planned, constructed, or operating in the flue gas stream of boilers fired with North Dakota lignite. North Dakota lignite has certain coal characteristics that are uniquely different than Texas or Gulf Coast lignites, such as the larger proportion of organic matter and association of alkali, sodium specifically, with that organic matter.
- 5) Slipstream SCR reactors of the same design were installed at three power plants to test SCR for NO_x emissions control. One of the plants was cyclone fired with North Dakota lignite and the others with subbituminous coal. Deposition on the reactor surface after two months using the lignite was significantly greater; the deposits were rich in sodium, calcium, and sulfur. The tests confirmed catalyst blinding and

³⁶ As noted in section 3.1.1.2, contemporaneous with the Regional Haze SIP/FIP process, NDDH also prepared a BACT analysis for MRYS Units 1 & 2. In its BACT analysis, NDDH concluded that SCR was technically infeasible on a lignite-fired cyclone boiler, and selected SNCR as BACT. On December 21, 2011, the District Court issued a decision finding that the State's conclusion that SCR was not technically feasible was not unreasonable. See, U.S. v. Minnkota, 831 F. Supp. 2d at 1127-30

³⁷ Findings and conclusions are summarized from the North Dakota Regional Haze SIP, Appendix B.5, pgs. 15-19.

³⁸ Although the BART determination specifically references Fort Union lignite, the findings would apply to all North Dakota lignites.

plugging, but did not provide rates for catalyst deactivation. Tests also indicated that the deposits causing blinding and plugging of pores contained more sodium compared to Powder River Basin (PRB) coal.

Based on these findings, NDDH concluded that additional pilot scale testing would be required to assess issues specifically associated with the North Dakota lignite-generated flue gas characteristics, including potential impacts associated with:

- the high level of soluble alkali in North Dakota lignite;
- the potential abrasive qualities of North Dakota lignite ash; and
- particle size and sticky nature of high alkaline North Dakota lignite ash.

The NDDH concluded that without pilot scale testing the long term NO_x reduction efficiency, the volume of the reactor, the catalyst pitch and life of catalyst, could not be predicted with a high degree of confidence. Noting that the BART Guidelines do not require source owners/operators to conduct extended trials to learn how to apply a technology on a totally new and dissimilar source type, and that technologies in the pilot scale testing stages of development are not considered as “available” for purposes of BART, NDDH determined that high dust SCR was not available, and thus, not technically feasible for units combusting North Dakota lignite.³⁹

Although the first planning period BART determinations, focused on North Dakota lignite-fired cyclone boilers (i.e., LOS Unit 2 and MRYS Units 1 & 2), technical issues regarding the high level of soluble alkali in North Dakota lignite, the particle size and sticky nature of high alkaline fly ash, and the potential abrasive qualities of North Dakota lignite ash would apply equally to wall-fired and tangentially fired boilers. Technical issues identified by NDDH during the first planning period would also apply to LOS Unit 1; therefore, findings and conclusions from the first planning period BART determinations (Regional Haze SIP, Appendix B.5) and the MRYS Unit 1 & 2 BACT analysis, are incorporated by reference into this four-factor analysis.

³⁹ *Id.* at pg. 19. NDDH reached a similar conclusion in its BACT determination for NO_x control on MRYS Units 1 & 2, finding that high-dust SCR had not been deployed on the same or a similar source, and that the flue gas characteristics of North Dakota lignite are significantly different from other sources that have applied high-dust SCR. The NDDH found that these unique characteristics present significant challenges to the successful application of high-dust SCR for NO_x control, and that pilot testing would be needed to evaluate applicability of the control technology. Thus, NDDH concluded that because high-dust SCR is neither “available” nor “applicable” to the MRYS units, the control technology was technically infeasible and excluded from consideration as BACT. (See, Best Available Control Technology Determination for Control of Nitrogen Oxides for M.R. Young Station Units 1 and 2, April 2010).

Based on a review of SCR installations on coal-fired boilers and a review of reported advances in SCR catalysts since the first planning period, deactivation rates due to soluble alkali compounds in the flue gas (including soluble sodium and potassium compounds) and the adhesive/cohesive characteristics and potential abrasive qualities of the North Dakota lignite-derived fly ash still remain a concern for North Dakota lignite-fired boilers. SCR has not been installed and successfully operated on a North Dakota lignite-fired boiler, and the bench scale and pilot-scale studies needed to better understand ash behavior and catalyst blinding/erosion with North Dakota lignite-derived fly ash, and to better understand catalyst deactivation mechanisms associated with high soluble alkali compound concentrations in the flue gas have not been required or completed. Pilot-scale studies are needed to evaluate these issues to inform the development of advanced catalyst formulations, and to support the engineering and design studies needed to mitigate for potential deactivation routes (e.g., removing soluble alkali compounds from the flue gas and SCR design considerations such as catalyst formulation, catalyst pitch, reactor velocity, and catalyst surface and volume). Pilot-scale tests and engineering/design studies have not advanced since the first planning period's exhaustive analysis. These issues have not been resolved since the first planning period and still remain a significant barrier to the design and successful operation of high dust SCR on North Dakota lignite-fired boilers.

The BART Guidelines state that “[a] control technique is considered available...if it has reached the stage of licensing and commercial availability.”⁴⁰ Commercial availability follows bench scale and laboratory testing and pilot scale testing. Consequently, the guidelines state that “you would not consider technologies in the pilot scale testing stages of development as ‘available’ for purposes of BART review.”⁴¹ Furthermore, source owners/operators are not expected to conduct extended trials to learn how to apply a technique on a dissimilar source type.⁴² These BART guidelines also apply as a recommendation for the development of the LTS in the Round II Determination and four factor analysis.⁴³ Because there are still unresolved issues associated with catalyst poisoning, catalyst blinding and plugging, and catalyst erosion; and engineering solutions have not yet been determined or demonstrated and the high dust configuration has not moved beyond pilot scale testing, high dust SCR is still not available, and thus, not a technically feasible NO_x control technology for LOS Unit 1 and 2.

⁴³ See, Draft EPA Guidelines, pg. 183.

Low-Dust Configuration

The low-dust configuration is typically located in the flue gas stream between a hot-side ESP and the air heater inlet. Employing this configuration would represent a relatively low level of exposure to fly ash (with the exception of submicron ash particles), but a potentially high level of vapor-phase alkalis, such as sodium. Also, the location of this configuration in the flue gas path is inherently in an optimal temperature range for SCR technology of 650°F to 750°F. However, the cold-side ESP employed at LOS Units 1 and 2 for particulate control would preclude the application of a normal low-dust SCR configuration at this unit. A corollary to the low-dust/hot-side ESP configuration is the low-dust/cold-side ESP configuration. However, this low-dust configuration would require both a capital cost-intensive and operating cost-intensive gas-to-gas heater to facilitate reheating the flue gas to 550°F to 600°F. Considering the expected SO₃ levels in the flue gas from this configuration at LOS Unit 1 or 2, a gas temperature of 600°F would be appropriate to prevent formation of ammonium bisulfate/sulfate in the catalyst bed, while still supporting an acceptable reaction rate for NO_x reduction. Furthermore, there are no examples of this configuration being implemented on a North Dakota lignite-fired unit. Therefore, considering these significant financial disadvantages and the uncertainties associated with the efficient capture of sodium constituents in the flue gas by the cold-side ESP, this type of configuration is not a technically feasible NO_x control option for application at LOS Units 1 and 2.

Tail-End Configuration

In the tail-end configuration, the SCR reaction vessel is located in the flue gas stream after the particulate and FGD control systems. The potential advantage of a tail-end SCR (TE-SCR) configuration at LOS is that the flue gas will have passed through the WFGD system prior to the SCR catalyst. As such, there is the possibility that the mass transfer mechanism that results in the capture of SO₂ will also capture some of the vapor-phase sodium and the sodium-enriched submicron particles, reducing the risk of catalyst poisoning and/or deactivation.

Successful operation of the tail-end configuration would also require a capital and operating cost-intensive gas-to-gas heat exchanger to reheat the flue gas from approximately 140°F downstream of the existing WFGD to approximately 550°F. Due to the limited removal efficiency of SO₃ across a WFGD, the formation of ammonia bisulfate (ABS) is of concern. As such, an additional in-duct heating element should be employed to raise the SCR inlet temperature to 600°F, using natural gas duct burners. Since LOS does not have natural gas on site, a new pipeline would have to be constructed for approximately 26 miles. After the flue gas passes through the SCR (at

approximately 550°F), it would pass through the hot side of the gas-to-gas heat exchanger to cool the flue gas to 150°F prior to the exhaust stack.

In addition, SO₃ emissions are expected to increase with a TE-SCR. SCR catalyst is known to oxidize SO₂-to-SO₃ as the flue gas passes through the layers of catalyst and has the potential to require additional air pollution control requirements for sulfuric acid mist. Therefore, if a TE-SCR is implemented, a hydrated lime dry sorbent injection (DSI) system could be required upstream of the WFGD to remove the potential increase in SO₃ from the SCR.

During the first planning period, NDDH initially concluded, based on preliminary information provided by SCR catalyst vendors, that the TE-SCR configuration would be a technically feasible option for units firing North Dakota lignite.⁴⁴ However, as part of the MRYS NO_x BACT determination process, detailed information describing the expected ash characteristics and flue gas characteristics was provided to two SCR catalyst vendors (CERAM Environmental, Inc. (CERAM) and Haldor Topsoe, Inc.). Based on their review of the data, both vendors concluded that they would not be able to provide a catalyst life guarantee for either low-dust or TE-SCR without pilot-scale testing.⁴⁵

During the BACT review process, both companies made statements bringing into question the technical feasibility of either low-dust or TE-SCR. For example, CERAM stated that the high levels of sodium oxide (Na₂O) in the ash for North Dakota lignite are not commonly found in subbituminous and bituminous coals which are fired in boilers equipped with SCR systems, and that it was unaware of any SCR application experience in the industry with the level and form of sodium in the North Dakota lignite-derived ash. CERAM stated further that small aerosol particles can penetrate and neutralize active catalyst sites even in dry conditions, and that catalyst installed even in low dust and tail-end locations can be poisoned from exposure to the high levels of phosphorous, sodium, and potassium found in the mineral analyses provided for the MRYS BACT analysis.⁴⁶ Similarly, Haldor Topsoe stated that the potential exists that physical deactivation due to catalyst blinding and plugging could be severe enough to make SCR a non-viable option for controlling NO_x emissions.

⁴⁴ See, North Dakota Regional Haze SIP, Appendix B.5, pg. 25.

⁴⁵ See, United States v. Minnkota, 831 F. Supp. 2d, at 1117.

⁴⁶ *Id.*

Based on information provided by SCR design engineering firms and SCR catalyst vendors, NDDH made the following findings and conclusions with respect to the technical feasibility of low-dust and TE-SCR on a North Dakota lignite-fired boiler:⁴⁷

- 1) There has never been a full scale SCR of any type installed on a facility that burns North Dakota lignite.
- 2) To determine technical feasibility of TE-SCR, one must compare the flue gas characteristics generated from firing North Dakota lignite to the flue gas characteristics of other source types to which these control technologies have been applied previously.
- 3) Flue gas characteristics of boilers firing North Dakota lignite are significantly different from other boilers where SCR has been applied.
- 4) North Dakota lignite contains high quantities of soluble sodium and potassium which can cause catalyst reaction site poisoning, blinding, and plugging of catalyst pores and channels, and that the soluble sodium and potassium can also form sulfates that can blind and plug the catalyst pores and plug the catalyst channels.
- 5) Both CERAM and Haldor Topsoe indicated that they would not provide a guarantee for the catalyst life without successful pilot scale testing being done.

Technologies in the pilot scale testing phase of development need not be considered as available control technologies. Based on the fact that SCR technology had not been installed nor effectively operated on an North Dakota lignite-fired unit, the lack of a commercially viable vendor guarantee, and the need to conduct pilot-scale testing to evaluate potentially significant operational and design issues, NDDH concluded that the use of SCR technology, including low-dust and TE-SCR, on the lignite-fired MRYS boilers would be technically infeasible.⁴⁸

Although the MRYS BACT determination, and the initial planning period BART determinations, focused on North Dakota lignite-fired cyclone boilers (i.e., LOS Unit 2 and MRYS Units 1 & 2), technical issues regarding the high level of soluble alkali in North Dakota lignite-derived flue gas would also apply to LOS Unit 1. Therefore, findings and conclusions included in the MRYS Units 1 & 2 BACT analysis and the initial planning period BART determinations (Regional Haze SIP, Appendix B.5) are incorporated by reference into this four-factor analysis.

Based on a current review of SCR installations on coal-fired boilers, and a review of reported advances in SCR catalysts since the first planning period, deactivation rates due to soluble alkali compounds in the flue gas

⁴⁷ Findings and conclusions are summarized from United States v. Minnkota, pgs 1115-1116.

⁴⁸ Best Available Control Technology Determination for Control of Nitrogen Oxides for M.R. Young Station Units 1 and 2, April, 2010, pg. 21.

(including soluble sodium and potassium compounds) still remain a concern for North Dakota lignite-fired boilers. TE-SCR has not been demonstrated on a North Dakota lignite-fired boiler, and there are still significant technical concerns associated with the availability of existing SCR catalysts on a lignite-fired unit. Catalyst in a TE-SCR will still be vulnerable to alkali poisoning, pore pluggage and premature catalyst deactivation, and it is not known whether the comparatively high levels of soluble sodium and potassium in North Dakota lignite will be effectively removed by the upstream WFGD. Furthermore, the potential exists for fine particulate remaining in the flue gas to get into the catalyst pores reducing catalyst activity. Pilot-scale studies are needed to better understand catalyst deactivation mechanisms associated with high soluble alkali compound concentrations in the flue gas have not been completed.

In order to understand the effect of North Dakota lignite-derived flue gas on TE-SCR catalyst, identify potential design solutions, and evaluate the technical feasibility and effectiveness of TE-SCR at LOS Unit 1 with any degree of certainty, pilot scale testing of the control configuration would be needed. Because there are unresolved issues associated with catalyst poisoning, it is very unlikely that Basin Electric could obtain a viable commercial offering for TE-SCR on LOS Unit 1 without extended pilot-scale tests.

During the first planning period NDDH determined that TE-SCR was not available, and thus, not a technically feasible NO_x control option for North Dakota lignite-fired boilers. Although the NDDH's control technology evaluation during the first planning period specifically focused on North Dakota lignite-fired cyclone boilers, technical issues regarding catalyst deactivation mechanisms associated with the high level of soluble alkali in North Dakota lignite would apply equally to wall-fired and tangentially-fired boilers. The administrative record developed during the first planning period, including the BART determinations and MRYS BACT analysis, supports the conclusion that TE-SCR is also not an available NO_x control option for LOS Unit 1. An evaluation of SCR installations and reported advances in SCR catalysts since the first planning period, coupled with the fact that TE-SCR has not been demonstrated on a North Dakota lignite-fired boiler, and the likelihood that Basin Electric could not obtain a viable commercial offering for TE-SCR without extended pilot-scale testing, continues to support the conclusion that TE-SCR is not an available NO_x control technology. Nevertheless, because the first planning period BART analysis (and the MRYS BACT analysis) focused on cyclone boilers, Basin Electric has elected to include TE-SCR as a potentially feasible control option and carry it forward to the cost impact evaluation (section 5.3.2) for LOS Unit 1. Based on controlled NO_x emissions achieved in practice at existing bituminous- and subbituminous-fired unit, S&L assumed that the TE-SCR control option could achieve an average controlled

NO_x emission rate of 0.05 lb/MMBtu. Due to the previous ruling on North Dakota lignite-fired cyclone boilers, SCR on will not be evaluated further on LOS Unit 2.

5.2.2.2 Optimized Selective Non-Catalytic Reduction

SNCR involves the direct injection of ammonia or urea ((NH₂)₂CO) at high flue gas temperatures (approximately 1,600°F – 2,100°F) in an oxidizing environment. The ammonia or urea reacts with NO_x in the flue gas to produce N₂ and water as shown below.

Flue gas temperature at the point of reagent injection can greatly affect NO_x removal efficiencies and the quantity of ammonia or urea that will pass through the SNCR unreacted (referred to as ammonia slip). In general, SNCR reactions are effective in the range of 1,600°F – 2,100°F. At temperatures below the desired operating range, the NO_x reduction reactions diminish and unreacted NH₃ emissions increase. Above the desired temperature range, NH₃ is oxidized to NO_x resulting in low NO_x reduction efficiencies.

Mixing of the reactant and flue gas within the reaction zone is an important factor to SNCR performance. In large boilers, the physical distance over which reagent must be dispersed increases, and the surface area/volume ratio of the convective pass decreases. Furnace geometry, urea spray coverage, and droplet size must be considered when developing good mixing of reagent and flue gas, delivery of reagent in the proper temperature window, and sufficient residence time of the reagent and flue gas in that temperature window. As the boiler cycles in load, the optimum injection region may change. Thus most facilities require multiple injection zones which are placed in and out of service as the unit ramps in load. This can include modifying the zones of injectors that are operating and different loads and temperatures.

Retractable multi-nozzle lances (MNLs) are sometimes used to improve SNCR performance, especially if the furnace exit flue gas temperatures are too high. The retractable lances allow injection into the appropriate temperature zone more so than wall injectors, depending on the unit load and temperatures. The MNLs also help improve performance by refining the spray pattern for quicker vaporization of the conveying water. MNLs are often used in conjunction with wall injection to provide optimized coverage while reducing reagent cost.

In addition to temperature and mixing, several other factors influence the performance of an SNCR system, including residence time, reagent-to- NO_x ratio, and fuel sulfur content. Increasing the normalized stoichiometric ratio (NSR) can improve NO_x removal. This is completed by increasing urea solution flow through the injectors or changing the concentration of urea in the solution. However, too high of reagent injection rates will increase the ammonia slip beyond the recommended 10 ppmvd limit. Above this concentration, there are expected to be major impacts to the formation of ammonia salts on the boiler tube banks, reducing heat transfer efficiency, and air heater baskets, causing corrosion.

Overall, the application of SNCR on pulverized coal or cyclone boilers is feasible due to having reasonable temperature windows and residence time; however, the potential NO_x reduction is boiler-specific. Based on the NDDH conclusions in the First Regional Haze Implementation Period, SNCR was determined to be cost-effective for NO_x control on Units 1 and 2. LOS Units 1 and 2 installed SNCR in 2014 and 2015, respectively, and started compliance with a new NO_x limit in April 2017. As such, SNCR systems on Units 1 and 2 have been operational during the baseline period. Therefore, confirmation of optimization of the existing system will be explored as an option on Units 1 and 2, since SNCR is included in the baseline.

Prior to implementing the SNCR systems on Units 1 and 2, LOS personnel tuned SOFA systems for better boiler stoichiometry control and installed combustion optimization systems. The effect of these two systems prior to implementation of the SNCR resulted in much lower NO_x formation in the Unit 1 and 2 boilers. As such, removal efficiencies of the SNCR are based on a pre-SNCR value which includes the benefit of modifications since the First Implementation Phase.

For LOS Unit 1, SNCR boiler computational fluid dynamics (CFD) modeling was completed to understand the best performance expected prior to implementation and tuning of the system. Based on the SOFA, LNB, and combustion optimization systems, SNCR was predicted to achieve 20% removal with an outlet NO_x rate just over 0.17 lb/MMBtu. Based on flow and NO_x CEMS data, average performance of the SNCR is currently slightly below 0.17 lb/MMBtu. As such, the current SNCR system is considered fully optimized based on the expected CFD modeling; any additional urea injection may result in negative impacts with ammonia slip emissions. Also, MNLs were initially modeled in addition to the wall injectors and were found to improve removal efficiency by another 6%; however, the optimal locations of the MNLs were determined to have physical interferences which would have limited the possibility of installation and thus were not installed. As such, MNLs are considered

technically infeasible as part of this evaluation. For these reasons, SNCR optimization is not considered to be a technically feasible NO_x control option for LOS Unit 1, and will not be evaluated further.

As discussed previously, the SNCR on LOS Unit 2 was implemented after SOFA tuning, combustion optimization, and four vent ports were relocated. As such, the pre-SNCR baseline emission rate is much lower than the 0.67 lb/MMBtu uncontrolled baseline reported in the First Implementation Phase. S&L and Basin Electric consulted SNCR OEMs to determine the expected SNCR performance for a cyclone boiler similar to LOS Unit 2, considering the pre-SNCR baseline. The OEM, who performed a significant amount of modeling when the SNCR system was being designed on Unit 2, suggested that the SNCR system could be further optimized. Improvement of the stoichiometry would be required, by relocating all cyclone vent ports. Additionally, due to revised temperatures within the boiler from the new SOFA, vent port relocations, and combustion optimizers, the current urea injection lances are recommended to be relocated for better utilization of the reagent.

By optimizing LOS Unit 2's SNCR system based on additional vent port relocation and SNCR injection lance relocation, the unit may be able to achieve an additional 10% reduction from the annual baseline NO_x rate or approximately 0.27 lb/MMBtu at the boiler outlet at full load. This is consistent with greater than 25% reduction from an estimated pre-SNCR NO_x rate. In this case for LOS Unit 2, the limiting factor for optimized SNCR operation is full load. Overall, it is expected that optimization of the Unit 2 SNCR system at all loads is a technically feasible option to reduce NO_x emissions and will be evaluated further.

5.2.2.3 Rich Reagent Injection

Similar to SNCR, the concept of RRI is to use a nitrogen-containing additive (urea) injected into a reducing environment to promote peak NO_x reduction efficiency. RRI is a commercial technology for cyclone boilers only, thus is not an applicable option for LOS Unit 1. In contrast to SNCR, RRI typically is applied with only one injection level in the lower furnace near the cyclone barrels (temperature window of 2000°F-2600°F). The technology requires a sub-stoichiometric oxygen concentration near the barrels at <0.95. This allows for a higher injection rate of reagent without oxidizing to NO_x due to the sub-stoichiometry. Injection at this location also creates lower level of excess NH₃ emissions (ammonia slip), while injecting at an NSR of 2.0-3.0.

Due to the changes of the lower furnace stoichiometry, RRI is often not a technically feasible option at lower loads. Once the stoichiometric ratio increases to >1.0, there is the potential for NO_x generation due to the reaction of

ammonia with oxygen, especially if the injection location and rate is not optimized. Based on these limitations, RRI alone is considered most effective at full load.

The RRI process is a commercially available process and has been predicted to typically reduce NO_x emissions by 20-40% at full load with no ammonia slip, but is highly dependent on the stoichiometry. However, this technology provides the most beneficial reduction at full load, due to the cyclone temperature window and stoichiometry. At mid- and low-loads, the predicted reduction is less than the current SNCR baseline operation at these loads. Therefore, low load operation is considered the limiting factor of RRI alone and the effectiveness of RRI is marginalized at mid-loads. SNCR would still be needed to achieve a similar reduction at low load. As such, RRI on its own is not a technically feasible NO_x reduction technology due to its limited operating conditions throughout all load ranges and will not be considered further.

5.2.2.4 Optimized SNCR + RRI

While RRI alone will provide beneficial NO_x reduction at full load only, coupling RRI with SNCR will provide a balanced approach to NO_x reduction through all load ranges. RRI and SNCR injectors are located at different elevations of the furnace and in different temperature windows. The system utilizes a high urea injection rate, staged at multiple locations throughout the boiler. The main advantage of this combined system is that the SNCR can provide better NO_x reduction at mid- and low-loads and at a lower NSR than RRI alone. Therefore, this combined system is expected to be able to provide a lower emission rate through all load ranges.

Similarly to SNCR and RRI, the only way SNCR + RRI will provide beneficial results is by relocating the remaining vent ports and keeping the SOFA tuned. This relocation will change the lower furnace O₂ stoichiometry, to be around 0.90 instead of 1.0. Due to negative impacts to the boiler with regards to slagging, 0.90 is the lowest stoichiometry that the unit can operate consistently with target coal quality. At full load, RRI + SNCR was modeled to provide reduction from pre-SNCR emissions. However, as discussed previously, RRI provides the largest benefit at full load; therefore, low- or mid-load operation would be the limiting factor.

Boiler CFD modeling of the SNCR and RRI systems was previously conducted with different assumptions of SOFA and vent port relocation performance. However, S&L consulted the CFD modeling company to provide insight into what performance could be achieved with the revised pre-SNCR baseline NO_x emission rate. This information was also provided to an SNCR+RRI system OEM who suggested that an additional 43% reduction

from the annual baseline could be guaranteed at full load, which would provide an outlet emission rate of 0.17 lb/MMBtu. This is consistent with greater than 50% reduction from an estimated pre-SNCR NO_x rate.

Alternatively to the optimized SNCR case, low load operation is the limiting factor for SNCR+RRI performance. RRI becomes ineffective at low load and the OEM suggested that almost no NO_x reduction would occur at this load due to RRI. Initial modeling suggested that increasing the urea NSR to 3.0 at low load could achieve an additional 2% reduction, but there is a concern about ammonia slip rates with this operating profile.

The SNCR + RRI combination would require all new penetrations for the RRI system as well as the relocation of the existing SNCR system as discussed in 5.2.2.2. The RRI system will require a larger urea storage tank, additional water treatment equipment for solutionizing, additional pump forwarding capacity, new piping to lower boiler elevations, additional boiler penetrations, injectors, and all balance of plant related equipment. At the lower elevation for the RRI ports, the most optimal injection location happens to occur at the same elevation of the windbox. Therefore specialized retractable and cooled injection lances with windbox modifications would be required. This design creates engineering and operational challenges that are normally avoided by injecting reagent in more accessible areas of the boiler.

Overall, the implementation of an RRI system along with optimization of the existing SNCR system is a technically feasible NO_x control option on Unit 2. Based on input from previous CFD modeling and SNCR OEMs, it is expected that LOS Unit 2 could achieve an outlet NO_x rate of 0.22 lb/MMBtu with an ammonia slip of 10 ppmvd with vent port relocation, optimized SNCR, and RRI.

5.2.2.5 Gas Reburn

Gas reburn is a retrofit technique that has been used to control NO_x emissions from coal- and oil-fired boilers. Gas reburn involves combustion in three distinct zones within the boiler: (1) a primary combustion zone, where the primary fuel is fired using conventional burners; (2) a reburn zone, where secondary fuel, typically natural gas, is introduced into the boiler; and (3) an overfire air burnout zone.

In the primary zone of coal-fired boilers, coal is fired through LNBs, at a rate corresponding to approximately 80% to 90% of the total heat input. Natural gas reburn fuel is then injected above the primary combustion zone under fuel-rich conditions at a rate corresponding to approximately 10% to 20% of the total heat input (on a Btu/hour basis). The fuel-rich reburn zone creates a reducing (sub-stoichiometric) region within the boiler where the natural gas, principally methane, breaks down to produce hydrocarbon radicals (CH and CH₂). The

hydrocarbon radicals react with NO_x produced in the primary combustion zone to form nitrogen and water vapor. Because the natural gas is not completely combusted in the reburn zone, gases exiting the reburn zone will contain considerable CO and unburned hydrocarbons; therefore, additional OFA is introduced above the reburn zone to complete the combustion process.

Critical design parameters that affect the feasibility and performance of a gas reburn retrofit system include: (1) baseline NO_x concentration; (2) reburn zone temperature, residence time, and stoichiometry; (3) OFA burnout zone temperature and residence time; and (4) mixing of the reburn fuel and overfire air with the bulk flue gas.

Gas reburn can have a positive impact on emissions of NO_x ; however, in order to make a meaningful prediction of the NO_x removal capabilities at LOS, extensive testing at each unit would be required because the performance is significantly dependent upon boiler operating characteristics. In addition, lack of natural gas available on site precludes the ability to test and implement this control option on LOS Units 1 and 2, which use fuel oil as the startup fuel. As such, gas reburn is not considered a technically feasible NO_x control technology at LOS Units 1 and 2.

5.2.2.6 Innovative Technologies

$\text{NO}_x\text{Star}^{\text{TM}}$

The $\text{NO}_x\text{Star}^{\text{TM}}$ process, also known as selective autocatalytic reduction (SACR), uses a continuous controlled amount of ammonia-based reagent with relatively small amounts of hydrocarbon to reduce NO_x emissions. The hydrocarbon is introduced into the flue gas at the convective pass of the boiler, with elevated temperatures. At the elevated temperatures, the hydrocarbon auto-ignites to form a plasma of free radicals that auto catalyzes the reaction of NH_3 and NO_x to form N_2 and H_2O . The hydrocarbon and ammonia are added through banks of nozzles in the superheat or reheat sections of the boiler. The injection location is determined by the location of the temperature windows for the "plasma creation zone" as well as the reaction zone for the ammonia.

To date, only one full-scale demonstration has been conducted to evaluate the technology on utility-sized boilers similar to LOS. The process is an emerging NO_x control, and there is limited information available to evaluate its technical feasibility and long-term effectiveness on a large lignite-fired boiler. Potential NO_x removal efficiencies would be a function of NH_3 - NO_x mixing, flue gas temperature, flue gas composition, and residence time downstream of the injection lances.

Because this is an emerging technology, long-term full-scale demonstration testing is required to demonstrate its effectiveness at LOS. It is likely that extensive design engineering and testing would be required to evaluate the technical feasibility and long-term effectiveness of the control system. Detailed design of the lances, mixing, optimization of the reagent supply across the boiler convective pass, flue gas temperatures, and flow distribution would have to be studied. Interference with the tube pendants in the convective pass may also make this more difficult to install. Installing a hydrocarbon distribution grid may present a problem with large boilers because of the span needed to uniformly distribute the reagent, interference with the tube pendants in the convective pass, and an additional booster fan may be needed. As such, NO_xStar™ is not considered a technically feasible NO_x control technology at LOS.

PerNO_xide

PerNO_xide utilizes hydrogen peroxide (H₂O₂) to reduce NO_x emissions. Hydrogen peroxide is injected into the ducts ahead of the air preheater and oxidizes the NO to NO₂, which is then captured in a downstream FGD system. To date, the technology has only been tested on a pilot-scale, and it has not been demonstrated on any coal-fired boilers. It is likely that extensive design engineering and testing would be required to evaluate the scale-up potential and long-term effectiveness of the system on LOS. As such, PerNO_xide is not considered a technically feasible NO_x control technology at LOS.

LoTOX®

The LoTO_x system is a gas-phase, low-temperature oxidation system, wherein ozone is injected into the flue gas stream to oxidize NO and NO₂ to N₂O₅ before being removed in a WFGD. This highly oxidized species of NO_x is water-soluble and rapidly reacts with water to form nitric acid. The conversion of NO_x to nitric acid occurs as the N₂O₅ contacts liquid sprays in the WFGD. The nitric acid would react with the alkali compounds in the WFGD and would be eliminated via the WFGD waste and byproduct streams. The LoTO_x system requires on demand ozone generation from a liquid oxygen supply.

The LoTO_x system has been successfully applied in refinery applications however; there are no full-scale installations on coal-fired boilers. According to vendors, one coal-fired boiler demonstration on a 25-MW boiler was performed which showed 90% NO_x removal. It is likely that extensive design engineering and testing would be required to evaluate the scale-up potential and long-term effectiveness of the system at LOS. As such, LoTO_x is not considered a technically feasible NO_x control technology at LOS.

Water Injection

The principle behind this technology is to inject an atomized water spray into the high-NO_x production zones of a cyclone burner or in the core of the flame for other furnaces. The water spray reduces the temperature and results in lower NO_x production within this zone. Developers claim that water injection through burners used in tangential-fired and wall-fired units will also lower the flame temperature and, hence, lower NO_x production. However, only laboratory results are available to demonstrate this technology's effectiveness in coal-fired applications.

Water injection is well demonstrated for combustion turbine applications for NO_x reduction. However, there is insufficient experience and demonstration data in coal-fired applications. As such, water injection is not considered a technically feasible NO_x control technology at LOS.

5.2.2.7 Technical Feasibility Summary

Table 5-5 and Table 5-6 summarize the results of the feasibility evaluation of available control options for LOS Unit 1 and 2.

Table 5-5. Technically Feasible NO_x Control Options for LOS Unit 1

NO _x Control Option	Technically Feasible (Yes/No)	Control Percentage (Note 1)	Technical Feasibility Summary
Optimized Selective Non-Catalytic Reduction (SNCR)	No	0%	SNCR is not considered an available and technically feasible NO _x control technology for LOS Unit 1. Performance in the field was tuned to achieve the best computational model runs.
Rich Reagent Injection (RRI)	No	0%	RRI is not available on LOS Unit 1.
Optimized SNCR + RRI	No	0%	SNCR + RRI is not available on LOS Unit 1.
Gas Reburn	No	0%	Gas reburn is not considered an available or technically feasible NO _x control technology at LOS Unit 1.
Innovative Technologies: NO _x Star™ PerNO _x ide LoTO _x Water Injection	No	0%	Innovative NO _x control technologies are evaluated in Section 5.2.2.6. In all cases, the technologies have not been demonstrated on a large North Dakota lignite-fired boiler. Extensive testing and design engineering would be required to evaluate the technical feasibility and long-term effectiveness of each innovative control system on LOS Units 1 and 2. Therefore, the innovative NO _x control technologies are not considered available control options and are not technically feasible NO _x control options for LOS Unit 1.
Selective Catalytic Reduction (SCR)			
High-dust configuration	No	0%	Due to significant unresolved issues associated with catalyst poisoning, catalyst blinding and plugging, and catalyst erosion; and based on the finding that engineering solutions have not been determined or demonstrated and the high dust configuration has not moved beyond pilot scale testing, high dust SCR is not an available or technically feasible NO _x control technology for LOS Unit 1.
Low-dust configuration	No	0%	Because LOS Unit 1 is equipped with existing WFGD control systems, low-dust SCR has no practical application on the unit, and low-dust SCR is not considered an available or technically feasible NO _x control option for LOS Unit 1.
Tail-end configuration	Yes	82.8%	EPA's reconsideration of North Dakota's NO _x BART determination focused on cyclone boilers firing North Dakota lignite, and did not specifically address PC-boilers firing North Dakota lignite. Therefore, for consistency with the approach NDDH used during the First Implementation Period (i.e., assuming technical feasibility, TE-SCR will be carried forward to the four factor analysis on LOS Unit 1.

Note 1. Control percentage calculated using the uncontrolled NO_x emission rate and the achievable NO_x emission rate for each technically feasible control option.

Table 5-6. Technically Feasible NO_x Control Options for LOS Unit 2

NO _x Control Option	Technically Feasible (Yes/No)	Control Percentage (Note 1)	Technical Feasibility Summary
Optimized Selective Non-Catalytic Reduction (SNCR)	Yes	60%	SNCR is considered an available and technically feasible NO _x control technology for LOS Unit 2. Computational fluid dynamic modeling and temperature mapping of the boiler would be needed to confirm that the incremental reduction in NO _x emissions is achievable without creating unacceptable operational issues.
Rich Reagent Injection (RRI)	No	0%	RRI is not considered a technically feasible NO _x control option at all loads at LOS Unit 2.
Optimized SNCR + RRI	Yes	67%	SNCR + RRI is considered an available and technically feasible NO _x control technology for LOS Unit 2. Computational fluid dynamic modeling and temperature mapping of the boiler would be needed to confirm that the incremental reduction in NO _x emissions is achievable without creating unacceptable operational issues.
Gas Reburn	No	0%	Gas reburn is not considered an available or technically feasible NO _x control technology at LOS Unit 2.
Innovative Technologies: NO _x Star™ PerNO _x ide LoTO _x Water Injection	No	0%	Innovative NO _x control technologies are evaluated in Section 5.2.2.6. In all cases, the technologies have not been demonstrated on a large North Dakota lignite-fired boiler. Extensive testing and design engineering would be required to evaluate the technical feasibility and long-term effectiveness of each innovative control system on LOS Units 1 and 2. Therefore, the innovative NO _x control technologies are not considered available control options and are not technically feasible NO _x control options for LOS Unit 2.
Selective Catalytic Reduction (SCR)			
High-dust configuration	No	0%	Due to significant unresolved issues associated with catalyst poisoning, catalyst blinding and plugging, and catalyst erosion; and based on the finding that engineering solutions have not been determined or demonstrated and the high dust configuration has not moved beyond pilot scale testing, high dust SCR is not an available or technically feasible NO _x control technology for LOS Unit 2.
Low-dust configuration	No	0%	Because LOS Unit 1 and 2 is equipped with existing WFGD control systems, low-dust SCR has no practical application on the unit, and low-dust SCR is not considered an available or technically feasible NO _x control option for LOS Unit 2.

NO _x Control Option	Technically Feasible (Yes/No)	Control Percentage (Note 1)	Technical Feasibility Summary
Tail-end configuration	No	0%	Based on EPA's 2015 Notice of final action on reconsideration (see, 80 FR 8550), and the continued lack of demonstration testing and commercial guarantees, TE-SCR is considered to be a technically infeasible control option for LOS Unit 2.

Note 1. Control percentage calculated using the uncontrolled NO_x emission rate and the achievable NO_x emission rate for each technically feasible control option.

5.2.3 Evaluate Technically Feasible NO_x Control Options for Effectiveness

The technically feasible NO_x control technologies are listed in in descending order of control efficiency. Table 5-7 and Table 5-8 also provide control option-specific NO_x emission rates in terms of lb/MMBtu. Emission rates shown represent average emission rates that the control options would be expected to achieve during normal operations.

Table 5-7. Evaluate Technically Feasible NO_x Control Options by Effectiveness for LOS Unit 1 (Baseline Average Emissions)

Alt. No.	Control Technology	NO _x Emission Rate (Note 1) lb/MMBtu	% Reduction from Uncontrolled NO _x (Notes 2, 3)	NO _x Emission Rate (Note 1) lb/hr	NO _x Emission Rate (Note 1) tons/yr
A	Selective catalytic reduction (SCR) – tail-end configuration (Note 2)	0.05	83	82	292
--	Baseline (existing LNB / SOFA / SNCR)	0.15	47	255	905
--	Permit Limit	0.19 (30-day)	--		

Note 1. Emission rates shown represent average emission rates that the control options would be expected to achieve on an on-going long-term basis under normal operating conditions for LOS Unit 1. Emission rates are provided for comparative purposes, and should not be construed to represent proposed emission limits. Corresponding permit limits must be evaluated on a control system-specific basis.

Note 2. Percent reduction from uncontrolled pre-BART (SNCR/OFA) upgrade NO_x emission rate of 0.29 lb/MMBtu.

Note 3. TE-SCR has not been installed on a North Dakota lignite-fired unit, and extended trials would be needed to better understand the design and operation of TE-SCR on LOS Unit 1. Nevertheless, during the initial planning period, NDDH concluded that TE-SCR was a technically feasible NO_x control technology for a North Dakota lignite-fired boiler, and evaluated the costs and cost-effectiveness of the control system. For consistency with NDDH's conclusion from the first planning period, TE-SCR will be carried forward to the four factor analysis.

Corresponding permit limits must be evaluated on a control system-specific basis.

Note 2. Reduction from pre-BART (SNCR/OFA) upgrade NO_x emission rates of 0.67 lb/MMBtu.

5.3 NO_x COST OF COMPLIANCE (STATUTORY FACTOR ONE)

The economic analysis performed as part of the four factor analysis examines the cost-effectiveness of each technically feasible control technology, on a dollar per ton of pollutant removed basis. Annual emissions, calculated for a particular control device, are subtracted from baseline annual emissions to calculate tons of pollutant controlled per year. For units with existing controls, the base case represents existing baseline actual emissions. Annual costs for each control option are calculated relative to the base case by adding annual O&M costs to the annualized cost of capital and, if applicable, lost revenue due to extended outage required for installation of control equipment. Capital costs and lost revenues were annualized using a capital recovery factor based on an annual interest rate of 5.25% and equipment life of 20 years.⁴⁹ Cost effectiveness (\$/ton) of a particular control option is simply the annual cost (\$/yr) divided by the annual reduction in annual emissions (ton/yr). In addition to cost-effectiveness relative to the base case, the incremental cost-effectiveness to go from one level of control to the next, more stringent, level of control may also be calculated to evaluate the incremental cost effectiveness of the more stringent control.

⁴⁹ The assumed 20-year equipment life is consistent with the control system equipment life used by NDDH in its evaluation of NO_x and SO₂ control technologies for BART-eligible sources. (see, e.g., ND Regional Haze Final SIP, Appendix C.1, "BART Determination Study for Leland Olds Station Units 1 & 2, Basin Electric Power Cooperative, August 2006, pgs. 64 (NO_x controls) and 158 (SO₂ controls). See also, ND Regional Haze Final SIP, Appendix C4, "NO_x Best Available Control Technology Study for Milton R. Young Station Unit 1, Minnkota Power Cooperative, Inc., October 2006, pg. 3-22).

Capital and O&M cost estimates were developed for each of the technically feasible NO_x control options. The LOS Units 1 and 2 cost estimates are conceptual in nature; thus, S&L did not procure equipment quotes specifically for the Units 1 and 2 control system upgrades. Rather, equipment costs are based on conceptual designs developed for the retrofit control systems, preliminary equipment sizing developed for the major pieces of equipment (based on Units 1 and 2-specific design parameters, including typical fuel characteristics, full load heat input, and flue gas temperatures and flow rates), and recent pricing for similar equipment. S&L would characterize the cost estimates for the LOS Units 1 and 2 retrofit technologies as “concept screening” cost estimates generally based on parametric models, judgment, or analogy.

Control technology equipment costs for the retrofit options were developed by scaling cost estimates prepared by S&L for other similar projects. Major equipment costs were developed based on equipment costs recently developed for similar projects, and include the equipment, material, labor, and all other direct costs needed to retrofit the units with the control technology. Sub-accounts for the capital cost estimates (e.g., mobilization and demobilization, consumables, contractor G&A expense, freight on materials, etc.) were developed by applying ratios from detailed cost estimates that were prepared for projects with similar scopes.

Fixed O&M costs include operating labor, maintenance labor, maintenance material, and administrative labor. Variable O&M costs include the cost of consumables, including reagent, water consumption, and auxiliary power requirements.⁵⁰ Auxiliary power requirements reflect the additional power requirements associated with the operation of the new control technology (compared to the existing technology). All O&M costs reflect the incremental increase in O&M costs compared to the costs incurred to operate the existing SNCR systems.

In addition to the cost effectiveness relative to the base case, the incremental cost-effectiveness to go from one level of control to the next more stringent level of control will also be calculated to evaluate the cost effectiveness of the more stringent control.

5.3.1 NO_x Average Annual Economic Evaluation

Table 5-11 presents the capital costs and annual operating costs associated with building and operating each control system. Table 5-13 shows the average annual and incremental cost effectiveness for each control system. Annual

⁵⁰ Variable O&M costs are based on the future SO₂ coal of 3.66 lb/MMBtu.

operating costs included in Table 5-11 are based on actual baseline period capacity factors of 61% for Unit 1 and 68% for Unit 2. The emissions reductions and cost effectiveness values included in Table 5-12 are based on baseline emission rates and projected actual emissions for each control option. Additional cost details are provided in Appendix D.

Table 5-11. NO_x Control Cost Summary (Annual Average)

LOS Unit No.	Alt. No.	NO _x Control Option	Total Capital Investment \$	Annual Capital Recovery Cost \$/yr	Annual Operating Cost \$/yr	Total Annual Cost \$/yr
Unit 1	A	Selective catalytic reduction (SCR) – tail-end configuration	\$227,717,000	\$18,662,000	\$14,809,000	\$33,471,000
Unit 2	B	Optimized SNCR + RRI	\$8,562,000	\$702,000	\$3,594,000	\$4,296,000
	A	Optimized SNCR	\$3,089,000	\$253,000	\$549,000	\$802,000

Table 5-12. NO_x Emissions Control System Cost Effectiveness (Annual Average)

LOS Unit No.	Alt. No.	NO _x Control Option	Total Annual Cost \$	Expected Emission Reduction (Note 2) tons NO _x /yr	Average Annual Cost-Effectiveness (Note 2) \$/ton NO _x removed	Incremental Annual Cost-Effectiveness (Note 1) \$/ton NO _x removed
Unit 1	A	Selective catalytic reduction (SCR) – tail-end configuration	\$33,471,000	613	\$54,605	
Unit 2	B	Optimized SNCR + RRI (Note 3)	\$4,296,000	1,183	\$3,630	\$4,594
	A	Optimized SNCR (Note 3)	\$802,000	423	\$1,896	

Note 1. Incremental cost-effectiveness represents the incremental increase in annual costs (\$/yr) divided by the incremental increase in annual NO_x emissions reductions (tons/yr) between a control option and the next most effective option.

Note 2. Expected emission reductions and average annual cost-effectiveness based on baseline NO_x emission rate and capacity factor during baseline NO_x period for each LOS Unit.

Note 3. Costs have not been included in this analysis for the subsequent loss in net generation or the cost to purchase replacement power. These costs would need to be included.

Table 5-12 indicates that the average annual cost effectiveness of the technically feasible NO_x control option for Unit 1 is \$51,605 per ton (SCR – tail-end configuration); and for Unit 2 ranges from \$1,896 per ton to \$3,630 per ton NO_x removed.

TE-SCR system costs have been included for Unit 1 to remain consistent with the approach used by NDDH during the initial planning period. Based on preliminary cost estimates, the cost effectiveness of a TE-SCR system is approximately \$54,600 per ton. The high cost is driven by the high capital expenses required for implementation with limited expected annual NO_x reduction, due to a low baseline emission rate on Unit 1.

Optimization of the existing SNCR system on Unit 2 is expected to achieve approximately 10% NO_x reduction from baseline emission rates. The cost effectiveness of this option is approximately \$1,900 per ton. The cost is driven by the increased urea consumption and the relocation costs. If RRI is included in addition to the optimization of the SNCR, the cost effectiveness of the combined option is approximately \$3,600 per ton, with a reduction of 26% from baseline emission rates. Compared to the optimized SNCR alone, the incremental cost effectiveness is approximately \$4,600 per ton. Major increase to urea consumption rates with RRI is the driver of the cost for this option. It should also be noted that an additional \$5.5 million is required for the RRI system implementation, which is ineffective while the unit is operating at low load. The facility is often dispatched at low load. Furthermore, the optimized SNCR and optimized SNCR + RRI options will also affect the units' net plant heat rate since the amount of water that will be injected with the urea will negatively impact boiler efficiency. Costs have not been included in this analysis, due to time constraints, for the subsequent loss in net generation which would increase the cost effectiveness of these two options. It would be expected that there would be a greater negative impact with the SNCR + RRI option. If requested, updated costs can be provided to NDDH.

5.3.2 NO_x Potential-to-Emit Economic Evaluation

Table 5-13 presents the capital costs and annual operating costs associated with building and operating each control system; annual operating costs are based on the units operating at 100% capacity factor. Table 5-14 shows the average annual and incremental cost effectiveness for each control system with emissions reductions and cost effectiveness values based on 100% capacity factors and potential-to-emit emission rates. Additional cost details are provided in Appendix D.

Table 5-13. NO_x Control Cost Summary (Projected Future Maximum)

LOS Unit No.	Alt. No.	NO _x Control Option	Total Capital Investment \$	Annual Capital Recovery Cost \$/yr	Annual Operating Cost ^(Note 1) \$/yr	Total Annual Cost \$/yr
Unit 1	A	Selective catalytic reduction (SCR) – tail-end configuration	\$227,717,000	\$18,662,000	\$15,722,000	\$34,384,000
Unit 2	B	Optimized SNCR + RRI	\$8,562,000	\$702,000	\$4,868,000	\$5,570,000
	A	Optimized SNCR	\$3,089,000	\$253,000	\$739,000	\$992,000

Note 1. Annual operating costs based on baseline NO_x emissions and 100% capacity factor for each LOS

Table 5-14. NO_x Emissions Control System Cost Effectiveness (Projected Future Maximum)

LOS Unit No.	Alt. No.	NO _x Control Option	Total Annual Cost \$	Expected Emission Reduction tons NO _x /yr	Average Annual Cost-Effectiveness ^(Note 2) \$/ton NO _x removed	Incremental Annual Cost-Effectiveness ^(Note 1) \$/ton NO _x removed
Unit 1	A	Selective catalytic reduction (SCR) – tail-end configuration	\$34,384,000	1,205	\$28,528	
Unit 2	B	Optimized SNCR + RRI	\$5,570,000	1,748	\$3,186	\$4,075
	A	Optimized SNCR	\$992,000	625	\$1,588	

Note 1. Incremental cost-effectiveness represents the incremental increase in annual costs (\$/yr) divided by the incremental increase in annual NO_x emissions reductions (tons/yr) between a control option and the next most effective option.

Note 2. Expected emission reductions and average annual cost-effectiveness based on baseline NO_x emissions and 100% capacity factor for each LOS Unit.

Table 5-14 indicates that the average annual cost effectiveness of the technically feasible NO_x control option for Unit 1 is \$28,528 per ton (SCR – tail-end configuration); and for Unit 2 ranges from \$1,588 per ton to \$3,186 per ton NO_x removed.

TE-SCR system costs have been included for Unit 1 to remain consistent with the approach used by NDDH during the initial planning period. Based on preliminary cost estimates, the cost effectiveness of a TE-SCR system is

approximately \$28,500 per ton. The high cost is driven by the high capital expenses required for implementation with limited expected annual NO_x reduction, due to a low baseline emission rate on Unit 1.

Optimization of the existing SNCR system on Unit 2 is expected to achieve approximately 10% NO_x reduction from baseline emission rates. The cost effectiveness of this option is approximately \$1,600 per ton. The cost is driven by the increased urea consumption and the relocation costs. If RRI is included in addition to the optimization of the SNCR, the cost effectiveness of the combined option is approximately \$3,200 per ton, with a reduction of 26% from baseline emission rates. Compared to the optimized SNCR alone, the incremental cost effectiveness is approximately \$4,000 per ton. Major increase to urea consumption rates with RRI is the driver of the cost for this option. It should also be noted that an additional \$5.5 million is required for the RRI system implementation, which is ineffective while the unit is operating at low load. The facility is often dispatched at low load. Furthermore, the optimized SNCR and optimized SNCR + RRI options will also affect the units' net plant heat rate since the amount of water that will be injected with the urea will negatively impact boiler efficiency. Costs have not been included in this analysis, due to time constraints, for the subsequent loss in net generation which would increase the cost effectiveness of these two options. It would be expected that there would be a greater negative impact with the SNCR + RRI option. If requested, updated costs can be provided to NDDH.

6. TIME NECESSARY FOR COMPLIANCE (STATUTORY FACTOR TWO)

The time necessary for compliance is generally defined as the time needed for full implementation of the technically feasible control options. This includes the time needed to develop and implement the regulations, as well as the time needed to install the selected control equipment. The time needed to install the control equipment includes time for equipment procurement, design, fabrication, and installation. Therefore, compliance deadlines must consider the time necessary for compliance by setting a compliance deadline that provides a reasonable amount of time for the source to implement the control measure. Basin Electric assumes a greater or equal amount of time would be provided as during the first planning phase, which was five years.

Table 6-1 and Table 6-2 include estimated timeframes needed to implement each of the technically feasible controls. The estimated timeframes do not account for time needed for North Dakota to develop and implement the regulations; therefore, the scheduled activities identified below commence immediately after SIP approval and are subject to the maintenance outage schedules of the individual unit.

Table 6-1. SO₂ Emissions Control System Implementation Schedule

LOS Unit No.	SO ₂ Control Option	Alt No.	Design / Specification / Procurement (months)	Detail Design / Fabrication (months)	Construction / Commissioning / Startup / Training (months)	Compliance Date (months after SIP approval)
Unit 1	FGD Operational Improvements – Ca:S Stoichiometry (Note 1)	A	0	0	3	No later than 60 months
Unit 2	FGD Operational Improvements – Ca:S Stoichiometry and L/G Ratio (Note 1)	A	0	0	3	No later than 60 months
Unit 1 and 2	FGD Upgrades – pH Buffer Addition	B	4	4	4	No later than 60 months

Note 1. Although this option would not require design/fabrication and construction months, Basin Electric would need 2-3 months to update O&M manuals and personnel training for the change to the work practice of the existing WFGD systems.

Unit 1	Selective Catalytic Reduction (SCR) - Tail End Configuration	A	10	18	24	No later than 60 months

7. ENERGY AND NON-AIR QUALITY ENVIRONMENTAL IMPACTS (STATUTORY FACTOR THREE)

The primary purpose of the environmental impact analysis is to assess collateral environmental impacts due to control of the regulated pollutant in question. Environmental impacts may include solid or hazardous waste generation, discharges of polluted water from a control device, visibility impacts, increased emissions of other criteria or non-criteria pollutants, increased water consumption, and land use impacts from waste disposal.

7.1 ENVIRONMENTAL IMPACTS

LOS Unit 1 is currently equipped with combustion optimizer/LNB/OFA/SNCR for NO_x control and WFGD for SO₂ control. LOS Unit 2 is equipped with combustion optimizer/SOFA/SNCR for NO_x control and WFGD for SO₂ control. The limestone reactant used in a WFGD system reacts with SO₂ in the flue gas to form calcium sulfate and calcium sulfite solids. The solids are either recycled to the system for reuse or removed from the system as nonhazardous solid waste. The existing wet scrubbing system also requires water to slurry the limestone prior to injection into the absorber. Based on the design of the control system, LOS Unit 1 and 2 currently use approximately 75 gpm and 153 gpm of water, respectively to slurry the limestone (at full load). In addition the Unit 1 and 2 SNCR systems use approximately 9 and 30 gpm, of water, respectively to dilute the urea reagent before injection in the boiler. Collateral environmental impacts associated with the existing LOS Units 1 and 2 control systems include water consumption and increased solid waste generation. There were no collateral impacts associated with the LNB/SOFA/OFA systems.

Based on a review of potential non-air quality environmental impacts, no significant collateral environmental impacts were identified for any of the SO₂ and NO_x control options included in this evaluation except for the TE-SCR option. The TE-SCR catalyst oxidizes some of the SO₂ to SO₃ in addition to catalyzing the reaction between NO_x and ammonia. There could be the potential for increased SO₃ emissions with the use of a TE-SCR. The SO₃ will react with the moisture in the stack to form sulfuric acid emissions. In addition the TE-SCR options utilize ammonia as the reagent for the reactions with NO_x to occur. There will be some ammonia slip emission from a TE-SCR in the range of 2 ppm. There is no means to capture the ammonia slip emissions from the TE-SCR since it would be installed downstream of the existing WFGD system. The implementation of the optimized SNCR can also increase ammonia emissions.

It is generally understood from previous visibility modeling efforts that increased ammonia injection has the opportunity of providing additional ammonia to the atmosphere. This increased ammonia availability within the emitted plume itself is known to contribute to increased visibility impairment due to more direct formation of ammonium sulfate and ammonium nitrate, more so in the winter months where fine particulate formation is ammonia limited.

7.2 ENERGY IMPACTS

Options that include increasing the Ca:S ratio will increase the auxiliary power consumption due to increased recycle pump operation and the TE-SCR option will increase pressure drop through the control system, increasing auxiliary power requirements. Both of these options will adversely affect the unit's net plant heat rate (Btu heat input per MW_{Net} output).⁵¹ Consequently, heat input to the boiler would need to increase to compensate for the increased auxiliary power requirements while achieving the same net plant output, or net output from the unit would decrease. In addition, the optimized SNCR and optimized SNCR + RRI options will also affect the units' net plant heat rate since the amount of water that will be injected with the urea will negatively impact boiler efficiency. Costs have not been included in this analysis, due to time constraints, for the subsequent loss in net generation.

Although several of the control options have energy impacts, none of the impacts are considered significant enough as to disqualify any of the options from consideration in the four factor analysis. In order to account for potential energy impacts associated with each option, the auxiliary power cost associated with operating the control systems have been included as an annual operating cost in the economic impact assessment.

7.3 ENVIRONMENTAL / ENERGY IMPACTS SUMMARY

A summary of the Statutory Factor 3 environmental and energy impact analysis is provided in Table 7-1.

⁵¹ Heat rate represents the amount of heat input to the boiler (Btu) required to generate one megawatt (MW) net electric output and is reported as Btu/MW_{Net}.

Table 7-1. Summary of Energy and Non-Air Quality Environmental Impacts

Control Option	Collateral Environmental & Energy Impacts
Baseline	<ul style="list-style-type: none"> ➤ LOS Units 1 and 2 are currently equipped with WFGD and SNCR control systems. Optimized SNCR or SNCR + RRI	<ul style="list-style-type: none"> ➤ Increased water consumption ➤ Increased auxiliary power requirements and heat rate penalty ➤ Potential increase in ammonia slip emissions

8. REMAINING USEFUL LIFE (STATUTORY FACTOR FOUR)

The evaluation of technically feasible NO_x and SO₂ controls options should consider the source's "remaining useful life" in determining the costs of compliance. The remaining useful life is the difference between the date that controls would be put in place and the date that the facility permanently ceases operation. If the remaining useful life of the unit is shorter than the useful life of a particular control option, the remaining useful life should be used annualizing costs. If the remaining useful life exceeds the useful life of the control options, the remaining use life has no effect on the cost evaluation.

Under the current LOS resource plan, the remaining useful life of LOS Unit 1 and 2 is greater than 20 years. Therefore, the remaining useful life has no impact on the annualized cost of control under the current regulatory framework.

9. CONCLUSIONS

At the request of NDDH, a four factor analysis was prepared for LOS Units 1 and 2 for use in their Round II Determination. The analysis identified technically feasible SO₂ and NO_x control options for the units, and evaluated each of the control measures for the following four statutory factors:

1. The costs of compliance;
2. The time necessary for compliance;
3. The energy and non-air quality environmental impacts of compliance; and
4. The remaining useful life of any potentially affected anthropogenic source of visibility impairment.

The cost of compliance evaluation (Statutory Factor 1) prepared for SO₂ controls indicates that, from baseline emission rates, the average annual cost effectiveness of the technically feasible SO₂ control options for Unit 1 ranges from \$10,021 per ton (Alternative A) to \$17,948 per ton SO₂ removed (Alternative B), and for Unit 2 ranges from \$6,906 per ton (Alternative A) to \$13,946 per ton SO₂ removed (Alternative B) from historical baselines. When evaluating projected future maximum emissions reductions, the average annual cost effectiveness of the technically feasible SO₂ control options for Unit 1 ranges from \$18,200 per ton (Alternative A) to \$18,948 per ton SO₂ removed (Alternative B), and for Unit 2 ranges from \$13,444 per ton (Alternative A) to \$15,462 per ton SO₂ removed (Alternative B).

The cost of compliance evaluation prepared for NO_x controls indicates that, from baseline emission rates, the average annual cost effectiveness of the technically feasible NO_x control options for Unit 1 is \$54,605 per ton NO_x removed (Alternative A), and for Unit 2 ranges from \$1,896 per ton (Alternative A) to \$3,630 per ton NO_x removed (Alternative B) from historical baselines. When evaluating projected future maximum emissions reductions, the average annual cost effectiveness of the technically feasible NO_x control options for Unit 1 is \$28,528 per ton NO_x removed (Alternative A), and for Unit 2 ranges from \$1,588 per ton (Alternative A) to \$3,186 per ton NO_x removed (Alternative B). For Unit 2, Alternatives A and B will also affect the units' net plant heat rate since the amount of water that will be injected with the urea will negatively impact boiler efficiency. Both alternatives do not include additional costs that would be incurred due to the loss in net generation.

The time necessary for compliance (Statutory Factor 2) for the SO₂ control options ranges from 3 months (Alternative A) to 12 months (Alternative B). For NO_x control options, the time necessary for compliance ranges from 12 months (Alternatives A and B – Unit 2) to 52 months (Alternative A – Unit 1).

An evaluation of energy impacts and non-air environmental impacts (Statutory Factor 3) indicates that certain control options will increase auxiliary power requirements due to increased pressure drop, which would adversely impact net plant heat rate. Consequently, heat input to the boiler would need to increase to compensate for the increased auxiliary power requirements while achieving the same net plant output, or net output from the unit would decrease. Collateral environmental impacts include potential increases in water consumption, solid waste generation, sulfuric acid mist emissions and ammonia emissions.

Regarding remaining useful life (Statutory Factor 4), under the current Basin Electric resource plan, the remaining useful life of LOS Units 1 and 2 are considered to be greater than 20 years. Therefore, the remaining useful life has no impact on the annualized cost of control under the current regulatory framework.

Based on the results of the four factor analysis prepared for LOS SO₂ emissions reductions, WFGD Operational Improvements and WFGD Upgrades are cost prohibitive. The control cost evaluation indicates that the average cost effectiveness levels exceed \$6,900 per ton SO₂ removed. Therefore, Basin Electric is proposing that the existing WFGD systems on Units 1 and 2 represent appropriate controls for the Round II Determination.

The four factor analysis prepared for LOS Units 1 indicates that additional NO_x controls are cost prohibitive. The cost effectiveness of installing a TE-SCR system on Unit 1 is over \$28,000 per ton NO_x removed. Therefore, Basin Electric is proposing that the existing LNB / SOFA / SNCR system on Unit 1 represents appropriate controls for the Round II Determination. For Unit 2, the analysis indicates a cost effectiveness of \$1,600 ton for the optimized SNCR alternative. The implementation of the optimized SNCR decreases the actual hourly mass emission rate by approximately 100 lb per hr (from historical baseline emissions). However, it can increase ammonia emissions, and that effect would result in additional haze formation. As such, a 5th factor analysis (visibility improvement using modeling) is recommended for this option to determine whether there is any or only a trivial amount of visibility improvement. Basin Electric requests that the NDDH withhold their Round II Determination until the Western Region Area Partnership's cumulative modeling platform are available so that a visibility improvement assessment can be conducted. Basin Electric will then perform a comparative visibility improvement analysis between the two control alternatives and submit the results to the NDDH for consideration.

It is generally understood from previous visibility modeling efforts that increased ammonia injection has the opportunity of providing additional ammonia to the atmosphere. This increased ammonia availability within the emitted plume itself is known to contribute to increased visibility impairment due to more direct formation of ammonium sulfate and ammonium nitrate, especially in the winter months where fine particulate formation is ammonia limited. In fact, it is during the winter months that the NO_x emissions have a visibility effect; the observed (and modeled) nitrate haze during the warmer months with more park visitation is negligible. As a result of the future modeling analysis, the actual visibility benefit of the optimized SNCR alternative may be considered minimal if not de-minimis.

For the Round II Determination, no change to the current Title V Operating Permit is proposed for SO₂ emissions on either LOS Unit 1 or 2 and no proposed change to the NO_x emissions on LOS Unit 1. Table ES-3 includes a summary of the proposed Round II Determination's strategy for NO_x, assessed NO_x emissions on a 30-day rolling average basis and a proposed Round II Determination's emission rate on a 30-day rolling average basis for LOS Unit 2. The proposed emissions limits include compliance margin to account for items such as variability in the operating load profile.

Table 9-1. Proposed Round II Determination's NO_x Emission Rate

LOS Unit No.	Pollutant	Assessed Emission Rate lb/MMBtu ^(Note 2) (30-day rolling average)	Proposed Round II Emission Rate ^(Note 1) (30-day rolling average)	Control Technology
Unit 2	NO _x	0.27	0.30	Optimized SNCR System

Note 1. The proposed Round II Determination's emission rate is a 14% reduction from the current permit limit of 0.35 lb NO_x/MMBtu, 30-day rolling avg.

Note 2. The assessed emission rate represents the average emission rate that LOS Unit 2 would be expected to achieve on an on-going long-term basis under normal operating conditions.

APPENDIX A

NORTH DAKOTA DEPARTMENT OF HEALTH LETTER

May 2, 2018

RECEIVED MAY 04 2018

Mr. Mike Paul
Basin Electric Power Coop.
1717 E Interstate Avenue
Bismarck, ND 58503-0564

Re: Regional Haze
Second Planning Period

Dear Mr. Paul:

The Department of Health (Department) has begun work on the second planning period (Round 2) State Implementation Plan (SIP) for regional haze. In Round 1 of the regional planning process, the emphasis was on Best Available Retrofit Technology (BART) and making reasonable progress towards the national visibility goal. In Round 2, there are no BART requirements; therefore, we will focus on making reasonable progress. The reasonable progress analysis will be made using the four factors in Section 169A(g)(1) of the Clean Air Act:

The four factors are:

1. The cost of compliance
2. The time necessary to achieve compliance
3. The energy and non-air quality environmental impact of compliance; and
4. The remaining useful life of any existing source subject to such requirements

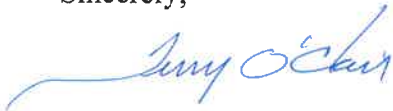

Guidance provided by the U.S. Environmental Protection Agency (Draft Guidance on Progress Tracking Metrics, Long Term Strategies, Reasonable Progress Goals and Other Requirements for Regional Haze State Implementation Plans for the Second Implementation Period at https://www.epa.gov/sites/production/files/2016-07/documents/draft_regional_haze_guidance_july_2016.pdf) indicates the Department must address 80% of the visibility impairment caused by in-state sources. Data from the IMPROVE monitoring sites at Theodore Roosevelt National Park (TRNP) and Lostwood Wilderness Area (LWA) indicate that sulfates and nitrates continue to be the largest contributors to visibility impairment in these areas. The primary precursors of sulfates and nitrates are emissions of sulfur dioxide (SO₂) and nitrogen oxides (NO_x).

Coal-fired electrical generating units have been identified as one of the largest source of sulfur dioxide and nitrogen oxides in North Dakota. Therefore, the Department requests that you prepare a "four factors" analysis for your coal-fired electrical generating units. The analysis should be prepared using the draft EPA guidance noted above. The Department will identify other sources in North Dakota that will be required to submit a four factors analysis.

The Department will be working with the Western Regional Air Partnership (WRAP) to prepare the Round 2 SIP. WRAP will be conducting air quality modeling of regional emissions reductions in early 2019. The Department asks that your "four factors" analysis be submitted by January 31, 2019.

If you have any questions, please contact David Stroh of my staff at (701)328-5188.

Sincerely,

A handwritten signature in blue ink, appearing to read "Terry O'Clair", with a long horizontal flourish extending to the left.

Terry L. O'Clair
Director
Division of Air Quality

TLO/TB:saj

Mr. James L. Semerad
North Dakota Department of Environmental Quality
918 East Divide Avenue, Second Floor
Bismarck, ND 58501-1947

Dear Mr. Semerad:

RE: Four Factor Analysis Updated Steam Costs for Leland Olds Station

As you are aware, Basin Electric Power Cooperative (Basin Electric) submitted a Round II Regional Haze Determination Four-Factor Analysis (Analysis) for the Leland Olds Station (LOS) on January 31, 2019. On July 26, 2019, Basin Electric submitted responses via e-mail to questions posed by the North Dakota Department of Environmental Quality (NDDEQ) regarding the Analysis.

Upon further review, Basin Electric has determined that the steam cost that was used in previous submittals was not accurate. Enclosed please find updated steam costs for LOS and revised cost-effectiveness of NOx reduction technologies reflective of this updated steam cost. This submittal is based on the best information Basin Electric has at this time. However, it is subject to change based on further analysis.

If you have any questions concerning this submittal, please do not hesitate to contact me at edukart@bepc.com or 701.557.5557.

Sincerely,

Erin Fox Dukart
Senior Environmental Compliance Administrator

NORTH DAKOTA ROUND II REGIONAL HAZE STATE
IMPLEMENTATION PLAN DETERMINATION'S FOUR-FACTOR
ANALYSIS FOR LELAND OLDS STATION
STEAM COST UPDATE

November 12, 2019

Project No. 13772-002

55 East Monroe Street • Chicago, IL 60603 USA • 312-269-2000
www.sargentlundy.com

In January 2019, Sargent & Lundy LLC (S&L) prepared a Round II Regional Haze Four-Factor Analysis for the Leland Olds Station (LOS) on behalf of Basin Electric Power Cooperative (Basin). The analysis was prepared in response to a request made by the North Dakota Department of Environmental Quality (NDDEQ) and included an assessment of potentially available sulfur dioxide (SO₂) and nitrogen oxide (NO_x) emission reduction technologies that could be applied to LOS Units 1 and 2. LOS Unit 1 is a nominal 220 MW lignite-fired pulverized coal steam electric generating unit equipped with low-NO_x burners (LNB), advanced separated overfire air (SOFA) and selective non-catalytic reduction (SNCR) for NO_x control and wet flue gas desulfurization (FGD) for SO₂ control. LOS Unit 2 is a nominal 440 MW lignite-fired cyclone boiler equipped with SOFA and SNCR for NO_x control and wet FGD for SO₂ control.

Based on a review of available technologies, one NO_x emission reduction technology was determined to be technically feasible and available to LOS Unit 1: (1) installation of tail-end selective catalytic reduction (TE-SCR). Furthermore, only two NO_x emission reduction technologies were determined to be technically feasible and available to LOS Unit 2: (1) optimizing the existing SNCR system; and (2) installation of rich reagent injection (RRI). SNCR technology reduces NO_x in the flue gas by utilizing a urea [(NH₂)₂CO] reagent. Aqueous urea solution is injected into the boiler where it is converted to ammonia (NH₃) which reacts with NO_x and oxygen to form molecular nitrogen and water vapor. The concept of RRI is similar to SNCR in that urea is injected into the boiler, specifically in the lower furnace to achieve NO_x reduction. Alternatively, SCR systems inject ammonia into the flue gas upstream of a catalyst bed to provide significant NO_x reduction. Operating costs associated with both SNCR and RRI include the cost of the urea and steam used to produce the urea solution, while TE-SCR utilizes steam to reheat the flue gas prior to the catalyst bed.

Following submittal of the Four-Factor Analysis, Basin requested that S&L revisit the steam cost that was used to develop operating costs for the technically feasible NO_x reduction technologies. The purpose of this supplemental report is to inform the NDDEQ of changes made to the steam costs and the impact of those changes on the cost-effectiveness of the NO_x reduction technologies. A brief description of the basis for the revised steam costs is provided as well as revisions to the steam cost calculations.

As part of the SNCR and RRI systems, liquid urea solution is injected into the boiler for NOx control. LOS currently purchases a dry urea for use in the existing SNCR which requires solutionizing prior to injection. As part of the urea solutionizing system, plant steam generated in the boiler is used to heat the reverse osmosis (RO) solutionizing water from 60°F to 165-180°F. Once the water reaches about 180°F it is transferred into a solutionizing tank. Dry urea is added to the solutionizing tanks via a dry urea connection at the top of each tank. Urea and heated water are added in a ratio to make a 50% aqueous solution of urea. The solution is mixed until the dry urea dissolves completely; a solutionizing pump then sends the solution to the urea storage tank(s).

S&L prepared the original four-factor analysis for different technologies based on an indicative steam cost of \$1.06/MMBtu for both LOS units. Subsequently, based on site-specific cost information provided by LOS, it became apparent that these indicative costs were substantially lower than the steam production costs specific to LOS. As such, this prompted S&L to revisit the analysis with a more accurate forecast of steam costs at LOS. Steam production costs include the cost of lignite fuel, fuel handling costs, and boiler efficiency. Fuel costs make up a majority of the cost of steam production. Efficiency is also considered in the costs, as not all the heat from combusting coal is transferred to steam, since there are various heat losses within the boiler island.

LOS reviewed their fuel and operating cost projections through 2028 associated with steam generation in the boilers. LOS forecasts a lignite cost of \$2.047/MMBtu in 2028 with fuel handling costs estimated to be \$0.137/MMBtu, resulting in a total fuel cost of \$2.184/MMBtu. In addition, LOS provided monthly operating reports for boiler efficiency on each unit. The average efficiency is approximately 80.43% and 82.25% for Unit 1 and Unit 2, respectively. These average efficiencies were used to calculate steam cost in conjunction with the fuel and material handling costs. As such, in order to account for the losses, nearly 20% more fuel is needed to generate the required steam for the urea solutionizing process. In conclusion, taking all the new site-specific information into account, the steam cost of \$1.06/MMBtu was revised to \$2.715/MMBtu for Unit 1 and \$2.655 for Unit 2.

Accounting for changes to steam prices and other adjustments as described in the letter submitted to the NDDEQ dated July 26, 2019, the revised cost effectiveness values are included below. Revised cost

effectiveness estimates are included in Attachment 1 for the annual average case and Attachment 2 for the future maximum case.

CONTROL TECHNOLOGY	NOx Control Cost Effectiveness (\$/ton)	
	Annual Average	Future Max

Erin:

I note in Table 4-6 of the Four-Factors analysis that the uncontrolled SO₂ emission rates assume all of the sulfur in the coal is emitted from the boiler. Based on the AP-42 emission factor for lignite, about 25% of the sulfur is retained in the bottom ash (varies depending on the sodium content of the ash). Using the AP-42 emission factor (30S), I calculate the uncontrolled emission rate at 2.80 lb/MMBtu. Since it is stated that 3.73 lb/MMBtu was used as the design basis for evaluating the SO₂ controls, it appears this section should be revised.

The Four-Factors analysis indicates that SNCR was placed in to service at Leland Olds Unit 1 in September 2017 and April 2017 for Unit 2. Your April 18th email regarding the WRAP Regional Haze modeling indicates the average NO_x emission rate from 2017-2018 was used. The 2028 projections for NO_x are somewhat higher than the baseline emissions in the January 30, 2019 Four-Factors analysis (1,267 tons versus 905 for Unit 1 and 4,718 tons versus 4,530 tons for Unit 2) while the SO₂ emissions essentially remained the same (700 tons versus 697 tons for Unit 1 and 1,371 tons versus 1,366 tons for Unit 2). Were the NO_x emission rates (1.892 lb/MW-net) and 3.376 lb/MW-net) calculated using data from the entire year - 2017 - or just the part of the year when the SNCR was operating? What is the reason for NO_x increasing but not SO₂?

I assume the baseline emission rates in the Four-Factors analysis will be updated to match the 2028 projections? The Four-Factors analysis sections on baseline emissions (2028 projections) should include the 2028 generation forecast as part of the justification.

Subject: RE: Leland Olds Station 4 Factor Analysis

Erin:

Thanks for the information.

I have reviewed the Leland Olds Station four-factors analysis and there are a couple of items that could be included in your resubmittal.

1. It is indicated that "Sargent and Lundy's conceptual cost estimating system" was used to develop certain costs. When

cost estimates are not based on EPA's Control Cost Manual, more documentation is required to substantiate the costs.
Please supply additional data to support these costs.

1. The Tables in Appendix C indicate an economic life of 20 years and an interest rate of 7% were used in the economic analyses (Appendix D indicates 20 years and 8% interest). The capital recovery factor listed appears to be based on 20 years and 5.25% interest (5.25% was suggested by the Department). The tables should be corrected.

If you have any questions, please contact me.

Mr. Bachman,

As you know, Basin Electric submitted Four Factor Analyses for the Leland Olds Station (LOS) and the Antelope Valley Station (AVS) on January 31, 2019. Since that submission, we have determined that the costs associated with Rich Reagent Injection (RRI) for LOS Unit 2 did not take into account the losses due to decreased efficiency. We are in the process of rectifying this oversight and determining what the appropriate and more accurate costs should be. We expect that analysis to be complete within the next few weeks and will submit it to the Department at that time. We apologize for any confusion as a result of this additional analysis, but wanted to let you know that it will be coming. If you have any **questions, please don't hesitate to contact me.**

Thanks,
Erin

Good morning,

Attached please find Basin Electric Power Cooperative's responses to the North Dakota Department of Environmental Quality's comments on the Leland Olds Station's Four-Factor Analysis. I apologize for not providing these responses to you sooner. If you have any questions or if there is additional information that we can provide, please contact me. The attachment contains the best information Basin Electric has at this time, but is subject to change based on further analysis.

Thanks,
Erin

NORTH DAKOTA ROUND II REGIONAL HAZE STATE
IMPLEMENTATION PLAN DETERMINATION'S FOUR-FACTOR
ANALYSIS FOR LELAND OLDS STATION
RESPONSE TO AGENCY COMMENTS

July 26, 2019
Project No. 13772-002

55 East Monroe Street • Chicago, IL 60603 USA • 312-269-2000
www.sargentlundy.com

Introduction

In January 2019, Sargent & Lundy LLC (S&L) prepared a Round II Regional Haze Four-Factor Analysis for the Leland Olds Station (LOS) on behalf of Basin Electric Power Cooperative (Basin). The analysis was prepared in response to a request made by the North Dakota Department of Environmental Quality (NDDEQ) and included an assessment of potentially available sulfur dioxide (SO₂) and nitrogen oxide (NO_x) emission reduction technologies that could be applied to LOS Unit 1 and 2. As a result, two NO_x emission reduction technologies were determined to be technically feasible and available to LOS Unit 2: (1) optimizing the existing selective non-catalytic reduction (SNCR) system; and (2) installation of rich reagent injection (RRI). The concept of RRI is similar to SNCR in that urea is injected into the boiler, specifically in the lower furnace to achieve NO_x reduction.

Following submittal of the Four-Factor Analysis, Basin requested that S&L perform a technical and economic evaluation of the potential impact to the efficiency and net plant heat rate of LOS Unit 2 with the installation of either of these two technologies. These updates account for heat rate impacts associated with the technologies. The adjustments made are based on industry experience which suggests that the additional water injected into the boiler with the urea solution will partially quench the heat generated and lower furnace temperatures, thereby decreasing boiler efficiency. A decrease to the boiler efficiency will increase the unit heat rate and require additional fuel to be fired to generate the same power output. As such, the impact of heat rate degradation due to SNCR and RRI is accounted for in the economic analysis by including purchase of additional fuel as replacement power as part of the facility's variable operating costs. For LOS Unit 2, the increased urea injection rate for the optimized SNCR is estimated to result in a 0.22% heat rate penalty, while the SNCR + RRI option is estimated to result in a 1.25% penalty. The difference in the heat rate penalty is due to the much higher water injection rate with RRI and the resulting temperature impact.

Furthermore, Basin requested S&L to revisit the effort required to implement the future potential RRI system, specifically with regards to the compressed air system. A significant amount of compressed air is utilized to atomize the urea for injection near the cyclones. Upon further review, the LOS operators determined that there would need to be significant expansion of the existing compressed air system, used for the existing SNCR, if RRI would be incorporated. In addition, review of the RRI lance location determined that there would need to be special modifications required based on OEM recommendation.

The RRI configuration for the removal rates referenced in the FFA would require windbox modifications for the lance penetration. As such, S&L revised the capital and operating cost expenses to incorporate the appropriate compressed air system expansion and windbox modifications.

In addition, NDDEQ tendered comments to Basin on April 15 and April 22, 2019, regarding the LOS Four-Factor Analysis. The purpose of this document is to provide responses to the April 15 and April 22 comments from NDDEQ, and to provide updated cost effectiveness tables for LOS Unit 2 (included in Appendix A and B attached hereto) that take into account costs associated with impacts to the net plant heat rate from the installation and operation of SNCR and/or RRI and the required compressed air system expansion.

NDDEQ Comment

It is indicated that “Sargent & Lundy’s conceptual cost estimating system” was used to develop certain costs. When cost estimates are not based on EPA’s Control Cost Manual, more documentation is required to substantiate the costs. Please supply additional data to support these costs.

S&L/Basin Response

S&L has considerable experience with the federal and state environmental regulations affecting power plant operations, as well as the specification, evaluation, selection, and implementation of emission control technologies for both gas- and coal-fueled utility power facilities, including extensive experience with air pollution control technologies. For example, since 2000, S&L has provided, or is currently providing, engineering services for the implementation of over 40 wet FGD projects, 30 dry FGD projects, 25 dry sorbent injection (DSI) projects, 60 selective catalytic reduction projects (SCR) and 30 selective non-catalytic reduction (SNCR) projects all of which are technologies that were analyzed as part of the Four-Factor Analysis.

Cost estimates for the Basin Four-Factor Analysis were, to the extent practical, prepared in accordance with the methodology described in EPA’s Control Cost Manual and represent study-level cost estimates. Capital costs for major equipment were developed using equipment costs for similar sized units (adjusted for actual equipment sizing), an approach allowed by the Control Cost Manual. Site-specific balance-of-plant (BOP) costs that LOS would incur to retrofit the control

system onto the existing unit were estimated based on site-specific general arrangements and project-specific indirect cost factors. Default factors from EPA's Control Cost Manual were used to calculate indirect capital costs, as applicable. Specifically, cost estimates were prepared with the following general approach and site-specific information:

- Boiler operating parameters were reviewed and mass balances were prepared to calculate flue gas flows across the range of operating conditions and to size the air pollution control equipment.
- Fuel characteristics were evaluated and used to size the material handling, material storage, and piping systems.
- Plant design data were used to estimate absorber sizing, reagent storage and preparation systems, dewatering systems and byproduct handling systems for air pollution control equipment.
- Aerial views of the plant and plant general arrangements were used to identify the general vicinity in which major equipment would be located.

The capital cost estimates were prepared for the major control system components, equipment, material, labor, instrumentation, etc. Capital costs were annualized using the methodology described in the Control Cost Manual, and annual operating and maintenance (O&M) costs were added to the annualized cost of capital to generate a total annual cost. Detailed cost effectiveness worksheets were provided identifying the O&M costs including, variable O&M costs (i.e. reagent, waste disposal, auxiliary power and water), indirect operating costs (i.e. property taxes, insurance, and administrative services), and fixed O&M costs (i.e. operating personnel as well as maintenance material and labor) for all of the air pollution control options. Default factors from EPA's Control Cost Manual were used to calculate fixed O&M costs, as applicable. The approach used by S&L to generate capital cost estimates, O&M costs, and total annual costs is in accordance with the methodology outlined in the Control Cost Manual.

NDDEQ Comment

The tables in Appendix C indicate an economic life of 20 years and an interest rate of 7% were used in the economic analyses (Appendix D indicates 20 years and 8% interest). The capital recovery factor listed appears to be based on 20 years and 5.25% interest (5.25% was suggested by the Department). The tables should be corrected.

S&L/Basin Response

NDDEQ is correct that the capital recovery factor used in the Four-Factor Analysis is based on a 5.25% interest rate and 20 years. While the worksheet implied 7.0% interest rate was used, the calculation was correct by using 5.25%. S&L has provided cost effectiveness tables, correcting the typo, attached in Appendices A and B.

NDDEQ Comment

I note in Table 4-6 of the Four-Factor Analysis that the uncontrolled SO₂ emission rates assume all of the sulfur in the coal is emitted from the boiler. Based on the AP-42 emission factor for lignite, about 25% of the sulfur is retained in the bottom ash (varies depending on the sodium content of the ash). Using the AP-42 emission factor (30S), I calculate the uncontrolled emission rate at 2.80 lb/MMBtu. Since it is stated that 3.73 lb/MMBtu was used as the design basis for evaluating the SO₂ controls, it appears this section should be revised.

S&L/Basin Response

We appreciate the agency's comment regarding calculation of the baseline SO₂ inlet rate. S&L used projected future fuel analyses (sulfur and HHV) provided by Basin to calculate the baseline inlet SO₂ rate. Projections were based on the annual average fuel sulfur content and average heating value of the fuel for each year over the next 20 years, taking into account historical deviations seen in the coal quality. Coal data were provided to Basin by the Freedom Mine. The baseline SO₂ rate of 3.73 lb/MBtu represents the highest annual average SO₂ emission rate assuming 100% conversion of fuel sulfur to SO₂ and without taking into account any inherent SO₂ capture.

NDDEQ used the Fourth Edition Compilation of Air Pollutant Emissions Factors (AP-42) from 1985 to adjust the baseline inlet SO₂ rate. That edition of AP-42 includes an assumption for lignite fuels that, on average, 75% of the fuel sulfur will be converted to SO₂ (i.e. $3.73 \text{ lb SO}_2/\text{MBtu} \times 0.75 = 2.80 \text{ lb SO}_2/\text{MBtu}$). However, a more recent edition recommends using an emission factor of 30S (lb/ton) for lignite-fired cyclone boilers, where S = weight % sulfur content of the lignite on a wet basis (see, Fifth Edition Compilation of Air Pollutant Emissions Factors AP-42, Volume 1: Stationary Point and Area Sources, Chapter 1, Table 1.7-1). A conversion factor of 0.077 is used to convert from lb/ton to

lb/MBtu assuming an average lignite heating value of 6,500 Btu/lb. Using this approach, the inlet SO₂ rate would be calculated as: $(30) \times (1.23) \times (0.077) = 2.84$ lb SO₂/MBtu.

Although the report states that S&L used an uncontrolled SO₂ rate of 3.73 lb/MBtu as the design basis for the Four-Factor Analysis, this value was only used for the Projected Future Maximum Case. Uncontrolled SO₂ rates of 3.12 lb SO₂/MBtu and 3.05 lb SO₂/MBtu for Units 1 and 2 (see Table 4-4 of the Four Factor Analysis), respectively were used for the Actual Average Case. In addition, since the LOS units already have new wet FGD's the only technically feasible SO₂ alternatives are upgrades to the existing wet FGD systems which are primarily O&M driven. Variable O&M costs that are impacted include reagent consumption such as pH buffer and limestone. Variable O&M costs were based on uncontrolled SO₂ rates of 3.12 lb SO₂/MBtu and 3.05 lb SO₂/MBtu for Units 1 and 2, respectively for the Actual Average Case. The difference between 2.80 lb SO₂/MBtu and 3.12 or 3.05 lb SO₂/MBtu will not have a significant impact on the FGD cost-effectiveness analysis because the variable O&M costs are relatively small.

NDDEQ Comment

The Four-Factor Analysis indicates that SNCR was placed in to service at Leland Olds Unit 1 in September 2017 and April 2017 for Unit 2. Your April 18th email regarding the WRAP Regional Haze modeling indicates the average NO_x emission rate from 2017-2018 was used. The 2028 projections for NO_x are somewhat higher than the baseline emissions in the January 30, 2019 Four-Factor Analysis (1,267 tons versus 905 for Unit 1 and 4,718 tons versus 4,530 tons for Unit 2) while the SO₂ emissions essentially remained the same (700 tons versus 697 tons for Unit 1 and 1,371 tons versus 1,366 tons for Unit 2). Were the NO_x emission rates (1.892 lb/MW-net and 3.376 lb/MW-net) calculated using data from the entire year - 2017 - or just the part of the year when the SNCR was operating? What is the reason for NO_x increasing but not SO₂? I assume the baseline emission rates in the Four-Factor Analysis will be updated to match the 2028 projections? The Four-Factor analysis sections on baseline emissions (2028 projections) should include the 2028 generation forecast as part of the justification.

S&L/Basin Response

Basin to respond.

Re: Regional Haze
Second Planning Period

Dear Ms. Roth:

The Department of Health (Department) has begun work on the second planning period (Round 2) State Implementation Plan (SIP) for regional haze. In Round 1 of the regional planning process, the emphasis was on Best Available Retrofit Technology (BART) and making reasonable progress towards the national visibility goal. In Round 2, there are no BART requirements; therefore, we will focus on making reasonable progress. The reasonable progress analysis will be made using the four factors in Section 169A(g)(1) of the Clean Air Act:

The four factors are:

1. The cost of compliance
2. The time necessary to achieve compliance
3. The energy and non-air quality environmental impact of compliance; and
4. The remaining useful life of any existing source subject to such requirements

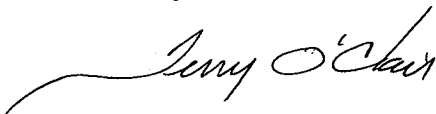

Guidance provided by the U.S. Environmental Protection Agency (Draft Guidance on Progress Tracking Metrics, Long Term Strategies, Reasonable Progress Goals and Other Requirements for Regional Haze State Implementation Plans for the Second Implementation Period at https://www.epa.gov/sites/production/files/2016-07/documents/draft_regional_haze_guidance_july_2016.pdf) indicates the Department must address 80% of the visibility impairment caused by in-state sources. Data from the IMPROVE monitoring sites at Theodore Roosevelt National Park (TRNP) and Lostwood Wilderness Area (LWA) indicate that sulfates and nitrates continue to be the largest contributors to visibility impairment in these areas. The primary precursors of sulfates and nitrates are emissions of sulfur dioxide (SO₂) and nitrogen oxides (NO_x).

Coal-fired electrical generating units have been identified as one of the largest source of sulfur dioxide and nitrogen oxides in North Dakota. Therefore, the Department requests that you prepare a "four factors" analysis for your coal-fired electrical generating units. The analysis should be prepared using the draft EPA guidance noted above. The Department will identify other sources in North Dakota that will be required to submit a four factors analysis.

The Department will be working with the Western Regional Air Partnership (WRAP) to prepare the Round 2 SIP. WRAP will be conducting air quality modeling of regional emissions reductions in early 2019. The Department asks that your "four factors" analysis be submitted by January 31, 2019.

If you have any questions, please contact David Stroh of my staff at (701)328-5188.

Sincerely,

Terry L. O'Clair
Director
Division of Air Quality

1 Introduction

Great River Energy (GRE) retained Barr Engineering Co. (Barr) to complete an updated analysis and evaluation of Best Available Retrofit Technology (BART) for NO_x emissions at Coal Creek Station Units 1 and 2. Barr is an environmental and engineering consulting services firm with over 800 employees founded in 1966 with ten offices located in the United States and in Canada. Barr has provided environmental regulatory and technical services to GRE associated with the regional haze regulations at Coal Creek Station and at Stanton Station since 2005.¹ Specifically, Barr completed the BART evaluation and report in December 2007 for Coal Creek Station as well as supplemental analyses and updates through 2012 that are appended to the North Dakota Department of Environmental Quality's (NDDEQ's) State Implementation Plan (SIP) for regional haze.² Barr has also completed several other BART analyses for facilities in the power industry and other industrial sectors in North Dakota and other states.

The purpose of this case-by-case BART analysis of NO_x emissions at Units 1 and 2 is to provide updated information to NDDEQ for the regional haze SIP record.

1.1 Overview of Steps and Factors for Conducting Case-by-Case BART

This case-by-case BART analysis for NO_x emissions at Units 1 and 2 updates and readdresses the five basic steps described in EPA's "Guidelines for BART Determinations Under the Regional Haze Rule" (EPA BART Guidelines).³

Barr has completed a dispersion modeling analysis using the CALPUFF modeling platform to evaluate Step 5 in the BART analysis. The corresponding dispersion modeling protocol for Step 5 is provided in Attachment E to this report.

The five steps are summarized as follows:

Step 1: Identify all Control Technologies

The first step in the analysis is to identify all available retrofit control technologies for each applicable emission unit.

¹ GRE has permanently ceased operations at Stanton Station, a 180 MW coal-fired power plant located just outside of Stanton, North Dakota. For informational purposes, Stanton Station's retirement results in an actual annual emissions reduction of 2,329 tpy SO₂ and 1,589 tpy NO_x based on the average annual reported emissions for the last five calendar years of plant operation (2012 to 2016).

² North Dakota Department of Environmental Quality (formerly the North Dakota Department of Health), "North Dakota State Implementation Plan for Regional Haze," Adopted February 24, 2010 as supplemented and amended through December 20, 2012.

³ 40 CFR 51, Appendix Y.

Step 2: Eliminate Technically Infeasible Options

In the second step, the technical feasibility of each control option identified in step one is evaluated with respect to source-specific factors. Technologies which are determined to be technically infeasible are eliminated from further consideration.

Step 3: Evaluate Control Effectiveness

In step three, the remaining controls are ranked based on the design control efficiency at the expected emission rate as compared to the emission rate before addition of controls.

Step 4: Evaluate Impacts and Document Results

The fourth step utilizes an engineering analysis to document the impacts of each remaining control technology option. The impacts analyses include: 1) costs of compliance, 2) energy impacts, 3) non-air quality environmental impacts, and 4) remaining useful life of the source.

Step 5: Evaluate Visibility Impacts

The fifth step simulates the degree of visibility improvement upon application of an additional emissions control technology. This study is conducted using the CALPUFF dispersion model.

Pursuant to the EPA BART Guidelines, application of the 5-step BART analysis *"identifies the best system of continuous emission reduction taking into account the following six factors:*

- 1) The available retrofit control options,*
- 2) Any pollution control equipment in use at the source (which affects the availability of options and their impacts),*
- 3) The costs of compliance with control options,*
- 4) The remaining useful life of the facility,*
- 5) The energy and non-air quality environmental impacts of control options, and*
- 6) The visibility impacts analysis."*⁴

For purposes of consistency with the Black & Veatch technical report in Attachment A, Barr consolidates and orders the BART factors as follows:

- Factor 1: Costs of compliance
- Factor 2: Energy and non-air environmental impacts
- Factor 3: Pollution control equipment in use at the source
- Factor 4: Remaining useful life of the source
- Factor 5: Visibility impacts

⁴ 40 CFR 51, Subpart Y, subsection IV.A.

The methodology for analyzing these BART factors is described further in Section 2. The recommended BART, summarized in Section 1.2, is based on technical conclusions described in this report for these five factors.

1.2 Proposed NO_x BART Determination for Units 1 and 2

In summary, based on our independent analysis and review of the attached third-party reports and the conservative nature of the cost analyses conducted for Factor #1, Barr concludes that potentially available additional NO_x emissions control technologies do not represent BART for Units 1 and 2.

- Selective catalytic reduction (SCR) is neither technically feasible as a retrofit control technology at Coal Creek Station nor is it cost-effective. Additionally, the estimated increase in sulfuric acid mist emissions due to an SCR system at Units 1 and 2 offsets much of the modeled visibility improvement that would otherwise occur from a reduction in NO_x emissions.
- Selective non-catalytic reduction (SNCR) is not cost-effective as well as potentially creates significant environmental impacts related to ammoniated fly ash.

Both SCR and SNCR pose serious risks that would need to be studied further through extensive pilot testing to determine if the technical concerns in Section 3.1.2 and 3.1.3 and adverse environmental impacts in Section 3.3 could be avoided or mitigated at Coal Creek Station.

Based on a review of recent emissions data with current emissions controls at Unit 2 and the anticipated completion of the same advanced combustion controls (LNC3+) for NO_x to be installed at Unit 1 in the first half of 2020, Units 1 and 2 are expected to perform under anticipated normal operations at an annual average emissions rate of 0.13 pounds of NO_x per million British thermal units heat input (lb NO_x/MMBtu). Variability in NO_x emissions during the year will continue to occur as a function of variable unit load (i.e., ramping in response to Midcontinent Independent System Operator or MISO) and the potential for low coal sodium concentrations (see Section 2.1). Taking into consideration these inherent variabilities affecting NO_x emissions performance in order to determine the shorter-term average (i.e., 30-day rolling average) emissions rate impact on NO_x performance, Barr recommends a BART emissions limit of 0.15 lb NO_x/MMBtu with compliance demonstrated using the existing 40 CFR 75 certified continuous emissions monitoring systems (CEMS).

2 BART Analysis Methodology

Barr has conducted an updated examination of the five BART factors for Coal Creek Station Units 1 and 2. Barr's analysis of Factors #1 through #4 considers information developed in recently completed detailed evaluations and technical reports produced by third-party subject matter experts. These reports are provided as attachments. They represent work by Black & Veatch for a Unit 2 NO_x BART evaluation of BART factors #1 through #4 in Attachment A and from Golder Associates (Golder) and Boral Resources (Boral) for impacts at Units 1 and 2 related to ammoniated fly ash in Attachments B and C, respectively. Section 3 of this report reviews and incorporates these analyses where relevant to the BART factors.

With respect to the Black & Veatch report, Barr provides additional analysis and context to their evaluation, where appropriate. For example, Black & Veatch estimated costs for available emissions control technologies using both the EPA Air Pollution Control Cost Manual⁵ (EPA Control Cost Manual) methodology and a "site-specific methodology" incorporating actual costs from installation at another source that are scaled to Coal Creek Station. Barr has completed its own evaluation of costs for available controls also using the EPA Control Cost Manual.

Section 2.1 summarizes the anticipated NO_x emissions rates from Unit 1 and 2 used to establish the anticipated annual emissions reduction from the application of additional emissions controls.

Sections 2.2 through 2.7 outline the approach to determining availability and technical feasibility of emissions controls and their corresponding impacts evaluated against the BART factors.

2.1 Current NO_x Emissions Performance Levels for BART Analysis

The EPA BART Guidelines at 40 CFR 51, Appendix Y state:

"The baseline emissions rate should represent a realistic depiction of anticipated annual emissions for the source. In general, for the existing sources subject to BART, you will estimate the anticipated annual emissions based upon actual emissions from a baseline period."

The initial BART evaluation used actual emission rates for the same time period used to determine the visibility baseline, which was a 3-year period of emission inventory data from 2000 to 2002. Due to the passage of time, this current BART analysis appropriately updates these emissions rates to reflect existing controls as well as updated operating conditions and emissions performance at Units 1 and 2. These updated NO_x emissions levels shall take into consideration the DryFining™ technology⁶ and any other

⁶ DryFining™ is an innovative technology developed by GRE that reduces moisture and refines lignite coal, increasing the efficiency and performance of the fuel while reducing emissions. It became operational at Units 1 and 2 in 2010.

combustion controls.⁷ Both units utilize “low NOx coal-and-air nozzles with close-coupled and separated overfire air,” which is referred to as LNC3. Since the time of the initial modeling conducted over a decade ago, Unit 2 installed larger registers;⁸ this system of additional separated overfire air, closed-couple overfire air, and low NOx burners, are together referred to as LNC3+.

Unit 1 is scheduled to install the same LNC3+ technology in the first half of 2020. Therefore, Unit 1 and Unit 2 are assumed to be equivalent in their NOx emissions performance for purposes of estimating emissions reductions from the implementation of control technologies assessed in this BART analysis. Since these two units are of the same size and design, the five-factor BART analysis in Section 3 is the same for Unit 1 and Unit 2. Correspondingly, Barr’s analysis and the referenced work by Black & Veatch, Golder, and Boral apply to both units.⁹

Unit 2’s annual NOx performance currently averages 0.13 pounds per million British thermal units (lb/MMBtu), which reflects an improvement in NOx emissions performance as compared to the time frame after LNC3+ was installed. Figure 2-1 illustrates 30-day rolling average NOx emissions levels on a parts per million (ppm) and lb/MMBtu basis at Unit 2 from January 1, 2018 to July 31, 2019. Actual NOx emissions during this time frame averaged 0.127 lb/MMBtu (rounded to 0.13 lb/MMBtu) with daily variability in NOx emissions between 0.10 and 0.19 lb/MMBtu. On a parts per million (ppm) concentration basis, the 30-day rolling average concentration varies from 52 to 68 ppm.

⁷ See also Great River Energy’s February 10, 2012 report, “Coal Creek Station Units 1 and 2 Best Available Retrofit Technology Refined Analysis for NOx Emissions.” Section 2.2.

⁸ Ibid. Larger registers allow for a greater ability to tune combustion staging and thus improve control of NOx emissions.

⁹ Black and Veatch conducted their analysis on Unit 2 only as it currently operates with LNC3+ and is thus also representative of future operation at Unit 1, which is expected to operate with LNC3+ by mid-2020. Effectively, Black and Veatch’s analysis and conclusions for Unit 2 are applicable also to Unit 1.

Figure 2-1: Unit 2 30-day Rolling NOx Emissions Performance (lb/MMBtu and ppm)

Operation of these combustion controls at Unit 2 have been demonstrated to be in a well-tuned state for combustion-based pollutants like carbon monoxide (CO) and NOx. A study¹⁰ was conducted by Alstom Power (now General Electric) in 2015 at Unit 2 to comply with the EPA’s Mercury Air Toxics Standards for Utilities (MATS) regulation. Alstom Power determined that the boiler with LNC3+ controls was found to be “well maintained and operated” and “well tuned for full load operation” while monitoring the flue gas for oxygen, NOx, and CO. Minor adjustments to oxygen levels had no effect on NOx emissions and any adjustments for the existing separated overfire air (SOFA) system settings resulted in increased NOx emissions. When Unit 1 is commissioned with LNC3+ controls next year, it also will be tuned to meet performance specifications, including for combustion pollutants. Barr recommends performing the commissioning and tuning process across the expected range of operating loads at Unit 1.

¹⁰ See Attachment A at Appendix H for “Unit’s #1 and #2 MATS Tuning Executive Summary Report”, Alstom Power, June 2015.

In a March 5, 2018, letter to the NDDEQ (see Attachment D), GRE noted two key operational factors that were inhibiting additional reductions in NO_x emissions at Unit 2:

- 1) Low sodium levels in the lignite provided by the nearby Falkirk Mine, and
- 2) Load variability when Coal Creek Station is required to ramp up and down based on demands from MISO, GRE's independent system operator.

An updated analysis of these factors, as applied to anticipated operations at Units 1 and 2, is provided in Sections 2.1.1 and 2.1.2.

Accounting for these operational factors and review of long-term actual NO_x performance levels that have been achieved in recent years, the annual NO_x emissions performance at Unit 2 (and at Unit 1 following LNC3+ installation in early 2020) is 0.13 lb/MMBtu for purposes of determining the emissions reduction effectiveness, costs, and other impacts of additional controls evaluated in Section 3.

2.1.1 Lignite Sodium Content Variability

There are two key variables that affect NO_x performance. One of them is lignite sodium content. GRE notes in the March 5, 2018 letter that low-sodium coal has a *"pronounced impact on the amount of slagging; as sodium levels drop, less slagging occurs."* Reduced slagging creates *"greater heat absorption in the lower zone of the boiler and less heat reaches the upper reheat and superheat zones of the boiler. This lowers unit efficiency and raises the heat rate. As a result, CCS2 (Unit 2) must burn more coal to produce the same amount of electricity."*

Since the time of this letter, GRE has been coordinating with the Falkirk Mine (Mine)¹¹ to help improve the minimum lignite sodium concentration to at least 2 percent sodium oxide (Na₂O) in the ash. The Mine works to support this and other lignite characteristics (i.e., heat content, ash, and sulfur) by manually blending lignite from multiple piles at the mine site. Sodium in the lignite ash is highly variable at the Falkirk Mine. Core samples taken at areas of the Falkirk Mine representing future (20-year projection) mine activity show sodium content data that range from less than 1% to over 14%.¹²

¹¹ The Falkirk Mine is owned and operated by North American Coal Corporation. It is a separate stationary source from Coal Creek Station under the Clean Air Act permitting programs.

¹² See Attachment A at Appendix A.4 for a chart summarizing the mine core sample sodium data.

Figure 2-2: Daily Lignite Ash Sodium Content (As-fired) from January 1, 2018 to July 31, 2019

Improvements made to support a minimum sodium content have helped to address the heat absorption and unit efficiency issues, resulting in improved lb NO_x/MMBtu performance. Figure 2-2 illustrates the daily as-fired sodium levels in the lignite ash at Coal Creek Station since 2018. However, sodium variability in the lignite fed to Units 1 and 2 will continue to occur based on Mine projections. At times, sodium levels are below 2 percent and at other times the levels are much higher than 2 percent, which creates other technical feasibility issues associated with add-on emissions controls. Specifically, higher sodium levels that will occur at times from the Falkirk Mine will cause ammonium bisulfate generation associated with SCR and corresponding deactivation of the SCR catalyst, as described in Section 3.1.2.

2.1.2 Unit Load Variability

The second key variable that affects NO_x performance is load variability. In the May 5, 2018 letter, GRE describes that Coal Creek Station, which was designed as a baseload generation plant, experienced an increasing number of load-following events due to increased production of renewable energy and grid pricing signals. The impact of load shifts such as ramping up or down or operating at low-load, causes an increase in NO_x emissions on a lb/MMBtu basis as compared to baseload operation.

More recently in 2018 and 2019, Units 1 and 2 have not been required to follow load as much, resulting in reduced cycling at night and corresponding reduced load variability. This, along with higher sodium levels in the lignite, have resulted in an improved NO_x performance level of 0.13 lb/MMBtu on an annual average. However, with the continued growth and reduced costs of renewable energy supply, changes in energy demand, and other market factors, it is reasonable to assume that future load variability at Units 1 and 2 may increase from levels experienced recently.

In summary, unit load variability is expected to continue and will be a critical consideration in estimating NO_x emissions levels with current emissions control technologies of DryFining™ and LNC3+ as well as for the technical feasibility of new emissions controls at Units 1 and 2.

2.2 Identify and Rank Available and Technically Feasible Retrofit Emission Control Technologies

Consistent with Steps 1 through 3 of the BART analysis (summarized in Section 1.1) and prior to completing a five-factor analysis of each emissions control technology via Steps 4 and 5, commercially available and technically feasible emission control options for Units 1 and 2 must first be identified and ranked in order of control effectiveness. Potentially available emission control options include both add-on control equipment and process improvement applications. All control options identified as available and technically feasible are then evaluated against the five BART factors.

In order to be considered available and technically feasible, an emissions control must have been previously installed and operated successfully on a similar source under similar physical and operating conditions. Novel controls that have not been demonstrated on full-scale, coal-fired utilities are not considered as part of this analysis. Instead, this evaluation focuses on commercially demonstrated control options.

For purposes of this analysis, only those technologies that have the potential to achieve an overall NO_x emissions less than 0.13 lb/MMBtu are considered. Importantly, the control effectiveness of a retrofit technology will generally not be as high for a unit that has relatively low NO_x emissions, like Coal Creek, as it would be for a unit with higher emissions. In other words, standard percent reductions may not be applicable and site-specific design considerations should be used when practical.

2.3 Factor #1 – Cost of Compliance

Factor #1 considers and estimates, as needed, the capital and annual operating and maintenance (O&M) costs of the control measure. Costs of emissions controls follow the accounting principles and methodologies in the EPA Control Cost Manual unless more refined site-specific estimates are available. Note that the methods in the EPA Control Cost Manual provide for a more simplified approach to estimate costs, but their application may not completely represent actual installation and operational costs due to site-specific considerations as described in this report. This is especially true for Coal Creek Station due to the location and operation of its unique DryFining™ and stack reheat systems, as described in Section 3.2.

Under Factor #1, the annualized cost of installation and operation, on a dollars per ton of pollutant removed (\$/ton) basis, of the control measure, referred to as "average cost effectiveness," is compared to a cost effectiveness threshold that is determined by the NDDEQ. Generally, if the average cost effectiveness is greater than the threshold, the cost is considered to not be reasonable, pending an evaluation of other factors.

The cost of an emissions control measure is derived using capital and annual operation and maintenance (O&M) costs. Capital costs generally refer to the money required to design and build the system. This includes direct costs, such as equipment purchases, and installation costs. Indirect costs, such as engineering and construction field expenses and lost revenue due to additional unit downtime to install the additional control measure(s), are considered as part of the capital calculation. Annual O&M costs include labor, supplies, utilities, etc., as used to determine the annualized cost in the numerator of the cost effectiveness value. The denominator of the cost effectiveness value (tons of pollutant removed) is derived as the difference in: 1) anticipated annual emissions using the current emissions control measures (baseline emissions), as described in Section 2.1, in tons per year (tpy), and 2) expected annual emissions performance through installation of the additional retrofit control measure (controlled emissions), also in tpy.

For purposes of calculating baseline emissions at each unit, GRE uses the annual NO_x performance level of 0.13 lb/MMBtu in conjunction with the maximum heat input capacity¹³ and projected annual utilization (also called annual capacity factor or ACF)¹⁴ of the unit to determine an annual tpy value. Over the past 10 years, Coal Creek Station averages 87% plant utilization, as shown in Table 2-1. GRE considers this value representative of projected operations for purposes of determining annualized emissions.

¹³ The represented nominal heat input capacity in Coal Creek Station's Title V Permit is 6,015 MMBtu/hr for Unit 1 and 6,022 MMBtu/hr for Unit 2, both of which are approximately equivalent to 605 MW nominal capacity at 10 MMBtu/MW (6,050 MMBtu/hr) that Barr uses in the cost analysis. At times, the short-term firing rate may exceed these values due to swings in lignite heat content and operating factors. These other values are reasonable for determining short-term (i.e., 24-hour) maximum actual emissions.

¹⁴ Annual capacity factor is defined by EPA (40 CFR 60 Subpart Dc) as "... the ratio between the actual heat input to a steam generating unit from an individual fuel or combination of fuels during a period of 12 consecutive calendar months and the potential heat input to the steam generating unit from all fuels had the steam generating unit been operated for 8,760 hours during that 12-month period at the maximum design heat input capacity..."

Table 2-1: Annual Average Capacity Factors at Coal Creek Station Unit 1 and Unit 2

Year	Annual Capacity Factor	
	Unit 1	Unit 2
2009	94.2%	92.7%
2010	93.8%	79.6%
2011	81.6%	89.0%
2012	92.4%	90.9%
2013	92.4%	83.3%
2014	87.8%	88.2%
2015	89.3%	87.3%
2016	86.3%	72.9%
2017	70.8%	85.0%
2018	91.6%	90.5%
10yr Average	88%	86%
Plant Average	87%	

The calculated cost effectiveness value for each control measure is compared to a cost effectiveness threshold established by the NDDEQ. The NDDEQ's original BART cost thresholds were based on the "high cost" value of \$3,000 per ton listed in the June 1999 WRAP Annex to Grand Canyon Visibility Transport Commission (GCVTC) Report.¹⁵ GRE scaled this 1999 value to today's dollars using the Chemical Engineering Plant Cost Index (CEPCI).¹⁶ The CEPCI is an industrial plant index that is considered more representative for purposes of this analysis than general cost indices such as the Consumer Price Index (CPI). The average cost effectiveness threshold in current dollars is calculated to be \$4,630 per ton.¹⁷

2.4 Factor #2 – Energy and Non-air Environmental Impacts

Factor #2 involves consideration of the energy and non-air environmental impacts of each control measure. Non-air quality impacts may include solid (ash) or hazardous waste generation and

¹⁵ Cited by EPA in the "Regional Haze Regulations and Guidelines for Best Available Retrofit Technology (BART) Determinations" proposed rule; 69 FR 25198; May 5, 2004.

¹⁶ More information on CEPCI may be found at this link: <https://www.chemengonline.com/pci-home>. The CEPCI is accessible by subscription through "Chemical Engineering" magazine. The CEPCI scaling factors for this analysis compare 1999 values to December 2018 values.

¹⁷ The NDDEQ also calculated an incremental cost effectiveness (cost effectiveness between two control measures) threshold in addition to the average cost effectiveness threshold for the BART evaluations. Barr does not use the incremental cost effectiveness criterion in the Factor #1 evaluation.

treatment/disposal, wastewater discharges from a control device, increased water consumption, and land use. The environmental impact analysis is conducted based on consideration of site-specific circumstances.

The energy impact analysis considers whether use of an emissions control technology results in any significant or unusual energy penalties or benefits. Energy use may be evaluated on an energy used per unit of production basis; energy used per ton of pollutant controlled or total annual energy use.

2.5 Factor #3 – Pollution Control Equipment at the Source

Factor #3 considers pollution control equipment in use or anticipated to be used in the near future at the source when determining the availability and impacts of additional retrofit controls. Section 2.1 describes the DryFining™ and LNC3+ technologies at Units 1 and 2 that correspond to a NO_x emissions performance of 0.13 lb/MMBtu. The evaluation of other control technologies shall consider the ongoing application of these technologies when determining if the additional control is effective in further reducing NO_x.

Because the NO_x emissions rate at Coal Creek Station of 0.13 lb/MMBtu is relatively low as compared to uncontrolled coal-fired units, the corresponding control efficiency for additional NO_x controls applied at Coal Creek Station will inherently not be as high. In order to provide a clearer understanding of NO_x emissions at the stack when evaluating additional controls in this evaluation, Barr examines the controlled emissions on a lb/MMBtu basis in relationship to the 0.13 lb/MMBtu value.

2.6 Factor #4 – Remaining Useful Life of the Source

Factor #4 is the remaining useful life of the source, which is considered to be the difference between the date that additional emissions controls will be put in place and the date that the facility permanently ceases operation. Generally, the remaining useful life of the source is assumed to be longer than the useful life of the emissions control measure unless there is an enforceable cease-operation requirement. In the presence of an enforceable end date, the cost calculation can use a shorter period to amortize the capital cost.

For the purpose of this evaluation, the remaining useful life of both Unit 1 and Unit 2 is assumed to be longer than the useful life of the additional emission control measures. Therefore, the expected useful life of the control measure is used to calculate the emissions reductions, amortized costs, and the resulting cost per ton (\$/ton).

2.7 Factor #5 – Visibility Impacts

The EPA BART Guidelines also require consideration of the degree of visibility improvement resulting from application of the retrofit technology when determining BART for an individual source. The CALPUFF program models how a pollutant contributes to visibility impairment with consideration for the background atmospheric ammonia, ozone and meteorological data. Additionally, the interactions between the visibility impairing pollutants NO_x, SO₂ and PM₁₀ (and the speciated components of particulate matter) can play a large part in predicting impairment.

Barr and GRE communicated with EPA Region 8 and the NDDEQ air quality staff to develop the dispersion modeling protocol for evaluating Factor #5.¹⁸ The dispersion modeling protocol and corresponding agency approval correspondence is contained in Attachment E-1 and E-2 to this report.

¹⁸ US EPA Region 8 provided draft comments on GRE's March 5, 2019 draft protocol document in April 8, 2019 correspondence from Monica Morales to Jim Semerad of the NDDEQ. Great River Energy provided responses to the comments on May 3, 2019, followed by a May 13, 2019 teleconference between staff at US EPA Region 8, NDDEQ, Great River Energy, and Barr Engineering Company.

3 Five-Factor BART NOx Analysis at Units 1 and 2

Section 3.1 identifies NOx emissions control technologies and summarizes available and technically feasible controls at Units 1 and 2 using Steps 1 through 3 of the BART analysis. Sections 3.2 through 3.6 evaluate each of the five BART factors for the retrofit control technologies that are assumed to be technically feasible.

For purposes of not duplicating the narrative in the other technical reports in Attachments A, B, and C, Sections 3.1 through 3.5 refer to these reports and add additional context or information based on Barr's independent evaluation.

Section 3.7 summarizes conclusions of this updated NOx BART analysis.

3.1 Identification and Ranking of Technically Feasible Retrofit Controls

Barr has conducted a review of potentially available NOx control technologies and evaluated the technical feasibility of NOx retrofit controls at Units 1 and 2.

3.1.1 Identification of Available NOx Controls at Units 1 and 2

In the 2007 BART Analysis¹⁹ for Coal Creek Station, Barr identified several potentially available NOx control technologies and conducted a corresponding technical feasibility analysis. In this update, Barr has reviewed its previous BART analyses contained in the NDDEQ's regional haze SIP record as well as Black & Veatch's recent evaluation provided in Attachment A. From this review, a few additional types of NOx control technologies, which are additional forms of catalytic reduction, were identified:

- Tri-Mer® UltraCat ceramic filters with SCR catalyst incorporated into the ceramic filter matrix.
- Fabric filter bags with SCR catalyst incorporated into the filter bags. Manufacturers include Haldor Topsoe CataFlex™ and Gore® DeNOx Catalytic Filter Bags
- Use of mid-temperature range SCR catalyst; this catalyst is capable of NOx reduction down to 300°F, potentially available from IBIDEN CERAM and Shell.

A technical feasibility evaluation of each of these additional emissions controls is described below in this section. None of these emissions controls are considered technically feasible for Coal Creek Station.

¹⁹ December 12, 2007, "Coal Creek Station Units 1 and 2 Best Available Retrofit Technology Analysis." This report is attached as Appendix C.2 to the NDDEQ's "North Dakota State Implementation Plan for Regional Haze", February 24, 2010.

In summary, consistent with Barr's findings in its earlier reports, the only available NO_x control technologies that could reduce annual emissions less than the 0.13 lb/MMBtu level described in Section 2.1 and that are potentially applicable to Coal Creek Station, pending the technical feasibility evaluation, is SCR and SNCR.²⁰ The technical feasibility and control effectiveness evaluation for these two types of emissions controls is provided in Sections 3.1.2 and 3.1.3, respectively.

The 2007 BART Analysis noted that wet scrubbing NO_x control technologies, such as Tri-NO_x and low temperature oxidation (LoTO_x™), were considered commercially available and were also presumed to be applicable (technically feasible) to a source type like Coal Creek Station. These technologies were not BART due to very high costs and significant environmental impacts (i.e., wastewater). Barr has since queried the EPA's RACT/BACT/LAER Clearinghouse (RBLC),²¹ which shows no such installations on large (greater than 250 MMBtu/hr) coal fired boilers to date. Because no known installations of these control types have been completed on a source type that is of similar size and with similar characteristics as at Units 1 and 2, these technologies are not technically feasible for BART and are not evaluated further. If these technologies were to be assessed against the five BART factors, Barr expects that the same conclusions would be made with respect to substantial economic and non-air environmental impacts.

UltraCat

The advantage of Ultra Cat is that the SCR catalyst is protected by being imbedded in the ceramic filter matrix. It is intended for high temperature applications such as glass manufacturing. Accordingly, it should be able to withstand the adverse effects of sodium in the boiler fly ash because the fly ash is filtered out before the flue gas can come in contact with the SCR catalyst particles. It is unknown at this time whether or not the sodium in the fly ash may cause plugging of the ceramic filter pores in the same way that sodium causes plugging in SCR catalyst pores.

UltraCat is not a viable retrofit option for Coal Creek Station, because it has not been implemented on a process that is close to the size of the Coal Creek Station boiler. Tri-Mer, UltraCat's manufacturer, indicates that the UltraCat modules are only capable of processing 30,000 actual cubic feet per minute (acfm) each and the maximum number of modules recommended per application is ten (300,000 acfm maximum). By comparison, the air flow rate out of the Coal Creek Station economizers exceeds 3,000,000 acfm at 830°F. Therefore, this technology is not feasible and is not further evaluated.

²⁰ The EPA BART Guidelines describe technical feasibility using two key concepts: "availability" (e.g., commercially demonstrated technology for sale) and "applicability." With respect to applicability, EPA describes the evaluation as follows: *"Generally, such a demonstration involves an evaluation of the characteristics of the pollutant-bearing gas stream and the capabilities of the technology. Alternatively, a demonstration of technical infeasibility may involve a showing that there are unresolvable technical difficulties with applying the control to the source (e.g., size of the unit, location of the proposed site, operating problems related to specific circumstances of the source, space constraints, reliability, and adverse side effects on the rest of the facility)."*

²¹ EPA's RBLC is accessed at <https://cfpub.epa.gov/rblc/index.cfm?action=Home.Home>

Catalytic Filter Bags

The advantage of catalytic filter bags is that the SCR catalyst is protected by enclosing the SCR catalyst inside a fabric filter bag. Catalytic filter bags are intended for multi-pollutant controls in applications where a fabric filter is used for particulate control. Thus, it should be able to withstand the adverse effects of sodium in the boiler fly ash because the fly ash is filtered out before the flue gas can come in contact with the catalyst.

Catalytic filter bags are not a technically feasible BART control for Coal Creek Station, because no known installations of this technology have been implemented on a process functionally comparable to the Coal Creek Station boilers. Additionally, Coal Creek Station uses electrostatic precipitators (ESPs) for particulate matter control instead of a baghouse, so this would require an entirely new baghouse complex with a corresponding extended several-month plant outage, which is impracticable and is thus not a viable retrofit option for further evaluation.

"Mid-Temperature" SCR Catalyst

Shell-CRI SCR catalyst is rated from 280°F to 750°F. IBIDEN CERAM indicates its SCR catalyst may be effective to a certain degree from 300°F to 1,050°F. The outlet temperatures of the Units 1 and 2 air preheaters are approximately 350°F.

However, these control applications in practice are for very-low-sulfur fuel based exhaust only (e.g., natural gas, scrubbed refinery fuel gas). IBIDEN CERAM confirmed that sulfur levels at Units 1 and 2 downstream of the ESP are too high for installing an SCR, especially at lower operating temperatures (300°F to 400°F) where ammonium bisulfate generation causes catalyst deactivation and plugging.

Effectively, the SO₂/SO₃ concentrations would need to be near 0 ppm for SCR to be viable for this option; otherwise, sulfuric acid would be formed as a side reaction on the SCR catalyst, ammonium bisulfate would form due to the reaction of ammonium and sulfuric acid, and catalyst plugging and deactivation would occur as a result. Therefore, this technology is not technically feasible at Units 1 and 2 and is not further evaluated.

3.1.2 SCR Technical Feasibility and Control Effectiveness Analysis

An SCR system has two types of arrangements: "high-dust" (reactor is located upstream of the particulate control system) and "low-dust" (reactor is located downstream of the particulate control system). In the 2007 BART Analysis, Barr ascertained that a high-dust system was technically infeasible at Units 1 and 2 "due to the likelihood of catalyst surface plugging caused by high sodium concentrations," and that "a low-dust SCR would require reheat to bring the stream temperature back to the effective range after it is cooled for particulate removal, but is a technical feasible option for NO_x reduction."

Barr's conclusion that a low-dust SCR is technically feasible (i.e., it is available and applicable to the source type) is unchanged with this update. The particulate controls will capture most of the sodium-bearing fly ash particles, and thus may mitigate SCR catalyst deactivation that is expected to otherwise occur with a

high-dust SCR. However, in order for the SCR to be most effective at controlling NO_x emissions from Units 1 and 2 that are already entering the system at a relatively low emissions rate (0.13 lb/MMBtu annualized), the exhaust gas from the outlet of the ESP must be reheated through a new fuel-fired reheat system to increase its temperature up to an SCR operating design of approximately 650°F. Subsequently, the gas leaving the SCR must then be cooled to the SO₂ scrubber inlet design temperature of 300°F. Designing and installing such reheating and cooling systems are expected to have significant economic impact and will have material environmental impacts due to associated air emissions from firing additional natural gas to reheat the exhaust. Barr believes that Black and Veatch's reported high-level cost estimate of the flue gas reheat and cooling systems at \$17 to \$20 million is reasonable, but actual installed costs may be higher than this when accounting for other site-specific factors. Therefore, a low-dust SCR will have a demonstrably higher economic impact than a high-dust SCR system, if the high-dust SCR system were determined to be technically feasible.

With respect to the technical feasibility of high-dust SCR, Barr's conclusion from 2007 that it is technically infeasible at Units 1 and 2 remains unchanged. Barr concurs with Black and Veatch's analysis and conclusion that an SCR catalyst supplier is unable to ensure reliable performance and catalyst life given significant concerns with potential plugging and catalyst deactivation unless extended trials (i.e., pilot testing with the exhaust characteristics of Units 1 and 2) are performed. The EPA generally does not consider a control technology to be technically feasible in this instance:²²

"Neither is it expected that an applicant would be required to experience extended trials to learn how to apply a technology on a totally new and dissimilar source type."

Given that the physical characteristics of the coal burned at Coal Creek Station and the associated exhaust gas stream flow and characteristics are outside the realm of installed SCR systems and because pilot testing and extended trials would be required to assess operational risks associated with catalyst deactivation, SCR is not technically feasible.

Notwithstanding that a high-dust SCR at Units 1 and 2 is not technically feasible for BART, Barr conservatively carries forward SCR into the five-factor BART evaluation to assess the related costs and non-air quality impacts of applying this technology at Coal Creek Station. In doing so, the five-factor BART evaluation for high-dust SCR effectively also covers the impacts of a low-dust SCR, noting that the economic impact of a low-dust SCR will be higher than a high-dust SCR due to reheat and cooling systems, as described above.

Barr completed an independent search of the RBLC database for utility-sized coal-fired boilers for SCR systems and performance levels. Determinations for Best Available Control Technology (BACT) and Lowest Achievable Emissions Rate (LAER) are generally more stringent than that for BART. Accordingly, the RBLC data provides information consistent with the best controls on recently constructed new and modified coal-fired utility boilers. Please see Attachment F for the RBLC summary tables. The RBLC listings range

²² USEPA, "Draft New Source Review Workshop Manual," October 1990, Page B.18.

from 0.05 to 0.25 lb/MMBtu with an average of 0.084 lb/MMBtu (9 listings). For comparison, Black and Veatch reports a SCR control effectiveness of 0.05 to 0.08 lb NO_x/MMBtu from their review of actual SCR performance data recently collected from the Western Regional Air Partnership (WRAP) and EPA's Clean Air Markets Division (CAMD). The only empirical data available to represent the best performance to be expected is that of existing large power plants burning Texas lignite, which achieve 0.062 to 0.075 lb/MMBtu annual performance levels per Black and Veatch's review of the WRAP data.²³ As these units are most representative of the actual performance at lignite-fired units, a range of SCR catalyst performance levels at 0.06 and 0.08 lb NO_x/MMBtu is established for purposes of the five-factor evaluation.

Actual SCR performance at Coal Creek Station is likely to not be as effective as at the Texas facilities based on the comparatively greater sodium content and other constituents of North Dakota lignite affecting the SCR catalyst as compared to that of Texas lignite. In the last two years, the as-fired lignite ash sodium content averaged 3% with variability generally of +/- 1% with deviation intermittently beyond these levels, as shown in Figure 2.2. The lignite ash sodium content has been and is expected, at times, to be greater than 4%, which is the maximum sodium percentage in IBIDEN CERAM's catalyst design.²⁴ Additionally, lignite ash sodium content data at the Falkirk mine, as summarized in Black and Veatch's report,²⁵ shows that 27% of all samples have a sodium content greater than 4% and that 9% of all samples were greater than 10% sodium content. By comparison, the sodium content in Texas lignite ash is consistently lower than that in North Dakota lignite ash. For example, one literature reference summarizes Texas lignite ash sodium levels between 0.59 and 1.67%, whereas North Dakota lignite ash sodium is shown as 5.8%.²⁶ In summary, the expected degradation and decreased performance of SCR catalyst in North Dakota lignite units is anticipated to be much more prevalent than at units firing lower sodium fuel like that in Texas.

Barr notes that the Black & Veatch report estimates the SCR control costs for a range of performance specifications at 0.04, 0.06, and 0.08 lb NO_x/MMBtu. The estimated performance level of 0.04 lb NO_x/MMBtu provided by the catalyst supplier was only for a one-time initial performance test. IBIDEN-Ceram, the SCR catalyst supplier, was uncertain of the degradation of catalyst performance over time in the presence of the high sodium content of the lignite coal burned at Coal Creek Station and required pilot testing to ascertain this critical design information during sustained operations. Correspondingly, Barr believes that 0.04 lb/MMBtu is not a demonstrable performance level for sustained operations at

²³ See Attachment A at Section 3.1 and Appendix F.

²⁴ See Attachment A at Appendix E.

²⁵ See Attachment A at Appendix A.4.

²⁶ The Babcock and Wilcox Company, "Steam: its generation and use," 41st Edition (2005), Chapter 9, Table 6 "Properties of U.S. Coals."

Coal Creek Station and that 0.06 lb/MMBtu is the best level of performance that can reasonably be expected based on established information to date.

Further, there are site-specific barriers to the installation of SCR at Coal Creek Station. The existing DryFinishing™ system and the stack reheat system²⁷ would need to be removed to tie SCR duct work into the boiler house and then be reconfigured, requiring an extended several-month outage, which is impracticable. Importantly, DryFinishing™ and stack reheat system are an integral part of the Coal Creek Station design to meet SO₂ BART requirements and must be preserved. DryFinishing™ also is used to remove moisture and improve the properties such as the heat content of lignite coal prior to combustion, thus improving NO_x performance and the energy efficiency of the Coal Creek Station boilers.

Finally, Barr acknowledges the technical feasibility work at Coal Creek Station that was completed by Fuel Tech, a company that provides emissions control technologies for power plants and other sectors, as summarized in the Black and Veatch report.²⁸ In examining application of their ASCR® hybrid technology, Fuel Tech also noted process concerns with sodium levels causing significant catalyst deactivation. Because of this and other concerns (e.g., spatial limitations), Fuel Tech would not recommend using its ASCR technology at Coal Creek Station and, at a minimum, would need pilot testing to determine catalyst operation and performance. Therefore, this technology is not further evaluated.

3.1.3 SNCR Technical Feasibility and Control Effectiveness Analysis

In its 2007 BART Analysis, Barr ascertained that SNCR technology is available and is applicable to the source type with an estimated emissions performance level of 0.108 lb/MMBtu. Since the time of this report, NO_x controls that have been (and will be) installed at Units 1 and 2, namely DryFinishing™ and LNC3+ combustion controls, will significantly decrease NO_x emissions to an annual level of 0.13 lb/MMBtu, as compared to 0.22 lb/MMBtu evaluated in the 2007 BART Analysis. A NO_x level of 0.13 lb/MMBtu at Unit 2 is generally equivalent to 65 ppm NO_x depending on fuel and operating conditions. The EPA Control Cost Manual for SNCR denotes several concerns:

- *"Sources with stable temperatures of 1550°F to 1950°F, uncontrolled NO_x emissions above 200 ppm, and residence times of 1 second are generally well suited to SNCR and attain the highest levels of NO_x control."*

This reported NO_x concentration is over three times the actual level at Coal Creek Station.

²⁷ The current Coal Creek Station exhaust stack is a dry stack and is not designed to accommodate water condensation in the stack. The reheat system is used to add sufficient heat to the stack to prevent water condensation for most operating conditions. Black and Veatch determined that the cost of replacing the existing stack with a new wet stack that could accommodate water condensation would cost at least \$16 million.

²⁸ See Attachment A at Section 2.2.13.

- *"Figure 1.8 shows an example of the NOx reduction efficiency that can be achieved for an uncontrolled NOx level of 120 parts per million (ppm) and various ammonia slip levels."*

In this figure, EPA shows that a high normalized stoichiometric ratio (NSR) is needed for the SNCR system to have a meaningful impact on NOx reductions at this uncontrolled concentration level, which is approximately twice that at Coal Creek Station.

A higher NSR results in increased ammonia slip. EPA notes several problems with ammonia slip, such as: *"Ammonia-sulfur salts can plug, foul, and corrode downstream equipment such as air heaters, ducts, and fans. Lastly, the ability to sell the fly ash as a secondary product is affected by its ammonia concentration."*

- *"Although there is significant scatter, Figure 1.1c shows a trend of increasing reductions with increasing baseline NOx levels for utility boilers. Specifically, the reductions range from 20 percent when the baseline NOx concentration is about 0.2 lb/MMBtu to 35 percent when the baseline NOx concentration is about 0.8 lb/MMBtu."*

Figure 1.1c for SNCR applied at coal-fired boilers shows no SNCR systems installed at boilers with an uncontrolled NOx level less than ~0.19 lb/MMBtu. By comparison, the current NOx performance level at Coal Creek Station is 0.13 lb/MMBtu. Even using the EPA-estimated 20 percent reduction from a 0.2 lb/MMBtu level results in controlled emissions that are higher than the current NOx performance level.

Barr completed an independent search of the RBLC database for utility-sized coal-fired boilers for SNCR systems and performance levels. Determinations for Best Available Control Technology (BACT) and Lowest Achievable Emissions Rate (LAER) are generally more stringent than that for BART, so the RBLC data provides information consistent with the best controls on recently constructed new and modified coal-fired utility boilers. Please see Attachment F for the RBLC summary tables. The RBLC listings range from 0.07 to 0.36 lb NOx/MMBtu (7 listings). However, five of these listings are for circulating fluidized bed (CFB) boilers, which are significantly different source type and exhaust characteristics that pulverized coal (PC) boilers like Unit 1 and 2. The two PC boilers with SNCR are shown with NOx performance levels of 0.35 and 0.36 lb/MMBtu.

For comparison, Black and Veatch reports a SNCR control effectiveness of 0.10 to 0.11 lb NOx/MMBtu from their review of Fuel Tech's site-specific assessment for SNCR at Unit 2. The SNCR proposal prepared by Fuel Tech is based on onsite testing of Unit 2 to collect data to prepare site-specific computational fluid dynamic (CFD) model and chemical kinetic model (CKM) of the boiler. Barr agrees with Black and Veatch's analysis and conclusion that SNCR NOx performance at Units 1 and 2 would be ~0.10 lb/MMBtu, at best, given that the chemical equilibrium of the SNCR reactions shifts and NOx re-formation rates make

it difficult to achieve further NO_x emission reductions.²⁹ The EPA SNCR Control Cost Manual also notes this limitation.

SNCR control is highly dependent upon boiler operating conditions and the ability of the control system to inject reagent into the boiler at optimal rates in the appropriate locations and at expected temperature and residence times. The Fuel Tech proposal indicates that their SNCR control system can be integrated with the boiler's control system to be load-following, which is an anticipated operating condition at Units 1 and 2 (see Section 2.1.2). In theory, the proposed Fuel Tech SNCR system should be able to achieve the NO_x reductions under routine variable loading, although they did not explicitly study it. As such, Barr considers the additional Multiple Nozzle Lances (MNL) option with its associated reagent injection rate and high stoichiometric ratio and ammonia slip from Fuel Tech as necessary elements for SNCR to address variable load conditions within the boiler.

3.2 Factor #1 Evaluation – Costs of Compliance

Barr has updated its cost evaluation from historical BART reports for high-dust SCR and for SNCR using the EPA Control Cost Manual methodology. Barr also has reviewed, for comparison, Black and Veatch's estimated costs for SCR and SNCR using both the general EPA Control Cost Manual methodology and a "site-specific methodology" incorporating actual costs from installation at another source that are scaled to Coal Creek Station. In summary, Barr's costs for high-dust SCR and for SNCR are comparable to Black and Veatch's estimates and would result in compliance costs that are much greater than the NDDEQ's cost effectiveness threshold.

3.2.1 SCR Cost Evaluation

Barr has populated the EPA SCR control cost spreadsheet with information relevant to Units 1 and 2. In doing so, it is noted that the EPA SCR control cost spreadsheets in this application will inherently underestimate the actual cost of SCR at Coal Creek Station. The EPA SCR cost correlations do not take into account the actual catalyst volume requirements, and resulting reactor size, for a specific application when calculating the cost of SCR. Based on the significant uncertainty of SCR catalyst performance and reliability under significant sodium variability conditions (see Section 2.1.1) at Coal Creek Station, IBIDEN CERAM's SCR catalyst proposal³⁰ and related communications with CERAM staff have identified that the specified catalyst volume is more than twice than that calculated in the EPA SCR Control Cost spreadsheet at a suggested performance level of 0.04 lb/MMBtu.³¹ The EPA SCR control cost spreadsheet cannot

²⁹ See Attachment A at Section 2.2.12, page 2-18 and Section 4.1.2, page 4-14.

³⁰ See Attachment A at Appendix E for IBIDEN CERAM proposal.

³¹ IBIDEN CERAM has requested that the actual catalyst volume be noted as business confidential but that it is at least twice the catalyst volume calculated in the EPA Control Cost Manual for reducing NO_x emissions at a Coal Creek Station unit from 0.13 to 0.04 lb/MMBtu, which is 24,433 ft³. The catalyst volume calculated using the EPA spreadsheet at 0.06 and 0.08 lb/MMBtu levels is less than this value because the volume is a function of NO_x emissions reduction.

readily be updated to accurately calculate the cost of SCR for CCS as it cannot account for the actual catalyst requirements recommended by the SCR catalyst supplier. Barr has not updated the spreadsheet to calculate the cost with catalyst volume and reactor size that reflects the IBIDEN CERAM's specification, and we note that the actual SCR cost is expected to be much higher than that calculated herein using the EPA spreadsheet.

As described in Section 3.1.2, Barr believes that a NO_x control effectiveness range of 0.06 to 0.08 lb NO_x/MMBtu on a sustained basis should be used in the control cost analysis due to the high potential for catalyst deactivation resulting from high sodium variability in the Falkirk lignite coal ash.

To be conservative (i.e., resulting in a lower estimated cost) in its estimate of catalyst replacement cost, Barr uses EPA Method 2 in the SCR Control Cost spreadsheet instead of EPA Method 1. Method 2 is an empirical correlation which estimates catalyst replacement costs based on industry experience. It relies on boiler capacity to estimate catalyst replacement costs. EPA Method 1 calculates the catalyst cost based on the anticipated catalyst replacement cycle. The EPA's recommended approach is to assume that one-third of the catalyst is replaced each year. However, the Coal Creek Station units normally operate on a 3-year maintenance outage cycle, so using the typical annual catalyst replacement cycle would not account for the costs and lost revenue of additional shutdowns for catalyst replacement. Following Method 1 assuming complete catalyst replacement at the end of the IBIDEN CERAM's estimated three-year life is consistent with Coal Creek Station's current operating practices, but results in a higher catalyst replacement cost. Method 2 is selected by Barr for determining catalyst replacement costs because it is generally representative of industry experience and results in a conservative (lower) estimated cost than the 3-year replacement cycle consistent with the IBIDEN-CERAM proposal.

Barr's estimates of control costs are summarized in Table 3-1.

Table 3-1: Barr's SCR Control Costs, per Unit Basis

NO _x Performance Level	Installed Capital Cost (\$)	Annualized Capital Cost (\$/yr)	Annual Operating Costs (\$/yr)	Total Annualized Costs (\$/yr)	Annual Emissions Reduction (tpy)	Pollution Control Cost Effectiveness (\$/ton)
0.06 lb/MMBtu	\$192 million	\$12.8 million	\$3.9 million	\$16.7 million	1,614	\$10,351
0.08 lb/MMBtu	\$180 million	\$12.1 million	\$3.4 million	\$15.4 million	1,153	\$13,391

In comparing Barr's estimate to Black and Veatch's estimate using the EPA Control Cost spreadsheets, Barr notes three primary differences:

- 1) The SCR catalyst cost used in the EPA spreadsheet must include the purchase cost, installation cost, spent catalyst removal cost and spent catalyst disposal costs. The catalyst cost of \$118/ft³ used in the Black & Veatch spreadsheets appears to include only the purchase cost and thus may underestimate actual costs. The EPA's default value of \$227/ft³ is recommended as it considers the other necessary catalyst activities.

- 2) Barr uses the gross MW rating of each Coal Creek Station unit to calculate the associated heat input and annual emissions (at 87% capacity factor) that are used to estimate the emissions reduction, whereas Black and Veatch uses a lower estimate from EPRI's Vista model.
- 3) Barr's estimated range of sustained NOx performance is 0.06 and 0.08 lb/MMBtu as described above. Black and Veatch also considered a performance level of 0.04 lb/MMBtu.

These differences do not change the conclusion that both Barr's and Black and Veatch's cost estimates are much greater than the cost effectiveness threshold of \$4,630/ton NOx removed.

Barr believes that a low-dust SCR will be more costly than the high-dust SCR due to the required reheat and cooling system that would need to be designed and installed. Therefore, the cost for a low-dust SCR is also much greater than the cost effectiveness threshold.

Black and Veatch also prepared a cost estimate using "site-specific methodology" from another project. Barr does not have access to the underlying data used to scale project costs and thus has no comments on the accuracy of the analysis other than to note that using actual project costs generally should provide more accurate results than default assumptions in the EPA Control Cost spreadsheet. Black and Veatch's cost effectiveness results for SCR at 0.06 lb/MMBtu is \$11,233/ton,³² which compares closely to Barr's estimate. Table 3-2 summarizes Barr's and Black and Veatch's results from the SCR cost effectiveness analyses.

Table 3-2: SCR Pollution Control Cost Effectiveness Summary, per Unit Basis

NOx Performance Level	Pollution Control Cost Effectiveness (\$/ton)		
	Barr Estimate using EPA Methodology	Black & Veatch Estimate using EPA Methodology	Black & Veatch Estimate using Site-specific Approach
0.04 lb/MMBtu	N/A	\$8,157	\$8,737
0.06 lb/MMBtu	\$10,351	N/A	\$11,233
0.08 lb/MMBtu	\$13,391	N/A	\$15,727

A critical physical complication with installation of SCR at Coal Creek Station that is not included in the cost effectiveness results above is the design of ductwork to accommodate the SCR. As described in the following points, both the existing DryFining™ system and the stack reheat system would need to be removed to tie SCR duct work into the boiler house and then be reconfigured, requiring an extended outage of 6 to 18 months as estimated by Black and Veatch.

- DryFining™ is used to remove moisture and improve the properties such as the heat content of lignite coal prior to combustion, thus improving NOx performance. This process also improves the

³² See Attachment A at Table 4-5.

energy efficiency of the Coal Creek Station boilers and reduces SO₂. DryFining™ is an integral part of the Coal Creek Station design to meet its SO₂ BART requirements. Therefore, this capability must be preserved. (See also Factor #3.)

- The current Coal Creek Station exhaust stack is a dry stack and is not designed to accommodate water condensation in the stack. The reheat system is used to add sufficient heat to the stack to prevent water condensation for certain operating conditions. For reference, Black & Veatch determined that the cost of replacing the existing stack with a new wet stack that could accommodate water condensation would cost at least \$16 million. This cost is not currently considered in the Table 3-1 estimate.

Effectively, these systems need to be removed and reconfigured in order to create space for installation of the SCR. Barr agrees with Black & Veatch's estimate that the plant outage would be approximately 6 to 18 months. The costs in lost revenue and in designing and implementing a reconfiguration of these systems are substantial and have not been included in the Table 3-1 estimate.

In summary, Barr believes that application of SCR is not cost effective for BART.

3.2.2 SNCR Cost Evaluation

Barr has examined the cost of an SNCR system by populating the EPA SNCR control cost spreadsheet with information relevant to Units 1 and 2. The EPA Control Cost Manual for SNCR and the associated spreadsheet estimate of the capital cost for SNCR are based primarily on size of the boiler and desired level of NO_x control. In this case, Barr uses the 0.10 lb/MMBtu performance level specified by Fuel Tech, noting that the necessary additional costs for multiple nozzle lances (MNL) to achieve this performance level are not part of the EPA Control Cost spreadsheet or methodology.

Barr's estimate of SNCR control costs is summarized in Table 3-3.

Table 3-3: Barr's SNCR Control Costs, per Unit Basis

NO _x Performance Level	Installed Capital Cost (\$)	Annualized Capital Cost (\$/yr)	Annual Operating Costs (\$/yr)	Total Annualized Costs (\$/yr)	Annual Emissions Reduction (tpy)	Pollution Control Cost Effectiveness (\$/ton)
0.10 lb/MMBtu	\$12.8 million	\$1.1 million	\$4.4 million	\$5.4 million	692	\$7,818

This cost effectiveness value aligns closely with that estimated by Black and Veatch using the EPA Control Cost spreadsheet and is more than 50% higher than the cost effectiveness threshold of \$4,630/ton NO_x removed.

Because the correlations used in the Control Cost Manual do not include an option to account for advanced design features like multiple nozzle lances (MNL) that are described in Fuel Tech’s proposal,³³ the EPA spreadsheet underestimates the actual expected cost. This difference is apparent when comparing the cost in Table 3-2 to the cost estimate from Black & Veatch using the site-specific methodology, which results in a cost effectiveness value of \$8,899/ton NOx removed. Barr believes that this estimate based on Fuel Tech’s proposal is more accurate than that using the EPA methodology and results in a cost that is nearly twice the cost effectiveness threshold. Table 3-4 summarizes Barr’s and Black and Veatch’s results from the SNCR cost effectiveness analyses.

Table 3-4: SNCR Pollution Control Cost Effectiveness Summary, per Unit Basis

NOx Performance Level	Pollution Control Cost Effectiveness (\$/ton)		
	Barr Estimate using EPA Methodology	Black & Veatch Estimate using EPA Methodology	Black & Veatch Estimate using Site-specific Approach
0.10 lb/MMBtu	\$7,818	\$7,279	\$8,899
0.11 lb/MMBtu	N/A	\$11,082	\$11,145

An important consideration for cost and environmental impacts that is not directly included in Barr’s or Black and Veatch’s cost estimates is the effect of SNCR ammonia slip on lost fly ash sales and added ash disposal costs. GRE currently sells its fly ash as a raw material for concrete production. In order to meet a NOx control level of 0.10 lb NOx/MMBtu with SNCR, ammonia slip concentrations estimated by Fuel Tech are expected to be between 5 ppm and 10 ppm. This representation is also consistent with the EPA Control Cost Manual for SNCR. An ammonia slip rate of 10 ppm is highly probable due to load variability (see Section 2.1.2) and will thus adversely affect the chemistry of the fly ash.

GRE commissioned Golder Associates (Golder) and Boral Resources (Boral), in conjunction with the Fuel Tech report of expected ammonia slip from installation of SNCR, to evaluate the potential for adverse impacts of ammoniated fly ash. Golder’s report in Attachment B concludes that higher ammonia concentrations in fly ash caused by SNCR create material risk in the marketability and sale of fly ash. To mitigate this risk of fly ash disposal instead of beneficial reuse, installation of an ammonia slip mitigation (ASM) technology is prudent. Boral has developed an ASM technology, noting that the technology is no longer in use and has not yet been applied to a large, lignite-fired unit. Boral could not provide a guarantee on the successful application of the technology at Coal Creek Station. See Attachment C for the Boral document.

Golder developed a conceptual design of ASM at Coal Creek Station. They note that there are potential conditions under which the ammonia concentration of the produced fly ash may not be treatable with the ASM system. Golder predicts a reasonable future scenario wherein an additional 20% of fly ash produced

³³ See Attachment, Appendix E for Fuel Tech proposal.

annually cannot be treated to acceptable levels and will thus need to be disposed instead of beneficially reused. Golder provides a cost estimate associated with these reduced sales and the application of the ASM technology. Barr agrees with Golder that, for budgeting and cost estimate purposes, the application of SNCR will require application of ASM technology and will result in an increase in fly ash that needs to be disposed. These costs have not been directly included in the current cost estimate to be conservative.

In summary, Barr believes that application of SNCR is not cost effective for BART even without considering the expected mitigation and disposal costs associated with ammoniated fly ash.

3.3 Factor #2 Evaluation – Energy and Non-Air Environmental Impacts

Barr has evaluated the energy and non-air environmental impacts associated with implementation of SCR and SNCR. In conjunction with our evaluation, Barr has also reviewed Black & Veatch's analysis of these impacts associated with these technologies as well as Golder's report of impacts due to ammoniated fly ash from SNCR.

A key environmental impact from high-dust SCR is the production of sulfuric acid as a side reaction with the SCR process chemistry. Sulfuric acid, which is not captured within the boiler or associated downstream emission control, is released to the atmosphere as sulfuric acid mist (SAM). In addition to causing an unsightly "blue plume" from the exhaust stack, SAM is emitted as aerosol particles that contribute to visibility impairment. Therefore, the visibility impacts of SAM emissions must be considered in the analysis of visibility improvements from SCR, or the costs of controlling SAM emissions must be included in the SCR control cost analysis. Using the calculation procedures in a 2018 publication from Electric Power Research Institute,³⁴ SAM emissions of approximately 415 tons per year per unit are estimated as a result of the SCR catalyst with a 5% oxidation rate at Coal Creek Station.³⁵ Calculations of estimated SAM generation due to SCR at Units 1 and 2 are provided in Attachment H-2.

A low-dust SCR will require a fuel-fired reheat burner system, which will result in additional energy usage and collateral air emissions of NO_x and other combustion pollutants.

Black & Veatch estimates the energy (due to auxiliary power consumption) and water consumption impacts of both technologies. The water demands for the SNCR system is estimated at 70 to 80 million gallons annually. Additionally, ammonia slip from these technologies will result in increased nitrogen in the scrubber that eventually is routed to the evaporation ponds. See Attachment A at Section 4.3 for a description of these impacts.

³⁴ See Attachment H-1. Electric Power Research Institute, "Estimating Total Sulfuric Acid Emissions from Stationary Power Plants," March 2018.

³⁵ The 5% oxidation rate was provided by IBIDEN CERAM and is referenced in Black and Veatch's report at Attachment A, Appendix E, Table 1.

Also for SNCR, Section 3.2.2 summarizes the risks due to increased fly ash disposal as a result of ammoniated fly ash. Golder estimates a scenario wherein an additional 92,000 tons annually of fly ash will need to be disposed in a landfill instead of beneficially reused, representing an 81 percent increase in the amount of fly ash disposed compared to current conditions.

In summary, the energy and environmental-related impacts from the application of SCR or SNCR at Units 1 and 2 are significant and support the conclusion that neither technology is BART.

3.4 Factor #3 Evaluation – Pollution Control Equipment at the Source

Section 2.1 describes the use of DryFining™ and LNC3+ combustion controls that define the annual NO_x performance level of 0.13 lb/MMBtu at Units 1 and 2 for purposes of determining emissions reductions due to additional retrofit controls. The current technologies are designed to be used for the foreseeable future.

3.5 Factor #4 Evaluation – Remaining Useful Life

Since Coal Creek Station will continue to operate for the foreseeable future, the EPA defined defaults for useful life of the SCR (30 years) and SNCR (20 years) are used to calculate emission reductions, amortized costs, and cost effectiveness on a dollar per ton basis.

3.6 Factor #5 Evaluation – Visibility Impacts

The visibility impairment contribution for different emission rate scenarios can be determined using the CALMET, CALPUFF, POSTUTIL, and CALPOST modeling tools. The modeling protocol at Attachment E-1 describes the emissions control scenarios to be evaluated and the CALPUFF model inputs, including the meteorological data set and background atmospheric ammonia and ozone concentrations along with the functions of the POSTUTIL and CALPOST post processing elements. The CALPOST output files provide two methods with which to assess the expected post-BART visibility improvement: the 98th percentile change in visibility, and the number of days on which a source exceeds an impairment threshold of 1.0 dV or 0.5 dV.

3.6.1 Determining 24-Hour Maximum Emission Rates for BART Emissions Control Scenarios

To be consistent with use of the highest daily emissions for pre-control visibility impacts, the emissions control scenarios reflecting the application of additional BART technologies to be used for the visibility impacts analysis should reflect the anticipated maximum 24-hour average basis. Emission rates and stack parameters for the emissions control scenarios used for visibility modeling are summarized in Table 3-3 and Table 3-4 and are described further in Attachment E-1. Note also that the generation of sulfuric acid

mist due to SCR is estimated in Attachment H-2 and is included in the modeled particulate matter emissions rate, consistent with EPA guidance.³⁶

In summary, the emissions control scenarios are as follows:

- Scenarios #0 and #1 reflect historical emissions controls at Units 1 and 2 that have since been upgraded to those identified in Scenario #2;
- Scenario #2 reflects current/anticipated emissions performance with DryFinishing™ and LNC3+ controls;
- Scenario #3 reflects the addition of SNCR to Scenario #2 at a performance level of 0.10 lb/MMBtu, and
- Scenarios #4A and #4B reflect the addition of SCR to Scenario #2 at a performance level of 0.04 and 0.06 lb/MMBtu, respectively.

³⁶ April 8, 2019, correspondence from US EPA to the NDDEQ on the draft modeling protocol at Comment #19: *"If evaluating SCR, we recommend that PM10 emissions be adjusted to account for the associated increase in sulfuric acid emissions (as a subcomponent of PM). See Estimating Total Sulfuric Acid Emissions from Stationary Power Plants, 2018 Update, Electric Power Research Institute, March 2018."*

Table 3-5: BART Eligible Sources Screening Analysis Emission Rates

Emissions Control Scenario	Unit	Emissions Control Technologies	Stack Parameters (see Table 3-4)	PM10 ⁽¹⁾ (lb/hr)	SO2 (lb/hr)	NOx (lb/hr)
#0 (2000 to 2002 Actual Emissions)	U1	LNC3	Pre SO ₂ BART	249.2	5733.5	1772.3
	U2	LNC3	Pre SO ₂ BART	216.1	4969.3	1822.4
#1	U2	LNC3, DryFining™, SO ₂ BART	Post SO ₂ BART	90.2	979	1233
	U2	LNC3, DryFining™, SO ₂ BART	Post SO ₂ BART	90.3	955	1233
#2	U1	LNC3+, DryFining™, SO ₂ BART	Post SO ₂ BART	90.2	979	898
	U2	LNC3+, DryFining™, SO ₂ BART	Post SO ₂ BART	90.3	955	898
#3	U1	LNC3+, DryFining™, SO ₂ BART, SNCR	Post SO ₂ BART	90.2	979	695

	U2	LNC3+, DryFining™, SO ₂ BART, SCR@0.06	Post SO ₂ BART	199.3	955	415

Note(s):

Modeled particulate for all Emissions Control Scenarios except #4 is speciated into the following component percentages: coarse (PMC = 32.0%), fine (PMF = 33.9%), secondary organic aerosols (SOA = 6.6%), elemental carbon (EC = 1.3%), and sulfate (SO₄ = 26.3%), using particulate speciation profiles for coal fired boilers as recommended by the National Park Service (NPS). For Emissions Control Scenario #4, consideration of sulfuric acid formation from the application of SCR technology contributes 109 lb/hr to the particulate emissions, modeled as sulfate.

Table 3-6: BART Eligible Sources Screening Analysis Stack Parameters

Unit	X Coord. ⁽¹⁾ (km)	Y Coord. ⁽¹⁾ (km)	Stack Height (m)	Base Elevation (m)	Stack Diam. (m)	Exit Velocity (m/s)	Exit Temp. (K)
Coal Creek 1 – Pre SO ₂ BART	63.387	376.062	201.0	602.0	6.7	25.9	358.5

3.6.2 Modeled Results

Visibility impairment is modeled using the meteorological data for the years 2000, 2001, and 2002 for the historical, current/anticipated, and BART emission scenarios. Results for the 98th percentile impacts and number of days above 0.5 dV and 1.0 dV at Lostwood Wilderness Area (LWA) and Theodore Roosevelt National Park (TRNP) North, South and Elkhorn Ranch units are summarized in Table 3-5 through Table 3-7.

As illustrated by the modeled visibility impacts, the future expected performance reflected in Scenario #2 for anticipated emissions controls and corresponding NO_x performance at Units 1 and 2 represents a significant improvement in facility-wide impacts from the original baseline. For example, the change in visibility impairment between Scenario #0 and Scenario #2 is generally between 1.0 to 2.0 Δ-dV on a 98th percentile comparison, depending on the Class I area and meteorological year.

The change in NO_x emissions rate between Scenario #2 and those scenarios representing additional controls evaluated in this report, Scenario #3 (addition of SNCR) or #4 (SCR), results in an average change of only ~0.1 Δ-dV on a 98th percentile comparison, depending on the Class I area and meteorological year. We also note that the sulfuric acid mist generated due to SCR has an appreciable impact on visibility impairment such that it effectively offsets much of the improvement in visibility that would otherwise occur from a reduction in NO_x emissions. In some cases, the visibility impairment is higher with SCR than with existing emissions controls modeled in Scenario #2.

3.7 Conclusion

After assessing and weighing the five BART factors and considering the conservative nature of the economic analysis performed, Barr concludes that additional NO_x emissions control technologies applied to Units 1 and 2, namely selective catalytic reduction and selective non-catalytic reduction, are not BART.

High-dust selective catalytic reduction (SCR) is neither technically feasible as a retrofit control technology at Coal Creek Station nor is it cost-effective with an estimated total capital investment of nearly \$200 million and an annualized cost that is over twice the cost effectiveness threshold. Additionally, the estimated increase in sulfuric acid mist emissions due to an SCR system at Units 1 and 2 offsets much of the modeled visibility improvement that would otherwise occur from a reduction in NO_x emissions. Low-dust SCR is also not cost-effective and has energy impacts and combustion emissions associated with a required fuel-fired reheat burner system.

Selective non-catalytic reduction (SNCR) is not cost-effective as well as potentially creates significant environmental impacts related to ammoniated fly ash.

Based on a review of recent emissions data at Unit 2 and the planned completion of installation of the same advanced combustion controls (LNC3+) for NO_x at Unit 1 in the first half of 2020, Units 1 and 2 are expected to perform at an annual average emissions rate of 0.13 pounds of NO_x per million British thermal units heat input (lb NO_x/MMBtu) using DryFining™ and LNC3+ emissions controls.

Taking into consideration these inherent variabilities affecting NO_x emissions performance and to determine the shorter-term average (i.e., 30-day rolling average) emissions rate impact on NO_x performance on a heat input basis, Barr recommends a BART emissions limit of 0.15 lb NO_x/MMBtu, which is less than the EPA's presumptive BART level of 0.17 lb/MMBtu on a 30-day rolling average.³⁷ This recommended limit is informed by actual NO_x emissions levels that have occurred at Unit 2 during "high load high sodium," "low load high sodium," "high load low sodium," and "low load low sodium" conditions. For example, the average hourly Unit 2 NO_x emissions at low load high sodium is 0.206 lb/MMBtu. Although GRE expects to operate primarily in high load high sodium, all of the other conditions are expected to occur at times in the future and will have an appreciable impact on the 30-day rolling average.

Figure 3-1 illustrates the effect of low load and low sodium on the 30-day rolling average. For example, an operating scenario may occur in the springtime (i.e., during mild weather) when Coal Creek Station is in a load-following mode for several days during a 30-day time frame. Considering the time for ramping up and ramping down and sustained low load conditions, it is reasonable to consider that a unit may operate in low load for several hours per day and for several days during the 30-day period. Based on the

³⁷ The EPA presumptive NO_x emission limit of 0.17 lb/MMBtu is at 40 CFR 51, Appendix Y, Section IV.E.5, Table 1, for a tangential-fired unit firing lignite.

interpolation of NOx emissions at high load and low load conditions (assuming high sodium during the 30-day period), GRE would be able to operate in low load mode for approximately 6 hours per day for the 30-day period in order to meet the 0.15 lb/MMBtu limit.

1.0 Introduction & Executive Summary

Great River Energy (GRE) contracted with Black & Veatch to assess four factors of the five-factor BART analysis of NO_x reduction technologies for their Coal Creek Station's Unit 2 ("Coal Creek Unit 2").¹ This report describes the assessment and its results.

Coal Creek Station consists of two coal-fired electric generating units. Both boilers are tangentially-fired boilers manufactured by Combustion Engineering (CE, now a part of General Electric, or GE), and each unit produces about 605 MW (gross) of power. Coal Creek Station is a mine-mouth facility located near Underwood, North Dakota and burns lignite coal from the co-located Falkirk Mine. The facility's annual capacity factor is 87% based on a 10-year average, which includes planned outages. Unit 2 has a nominal rating of 605 MW, and it currently emits 0.13 lb/MMBtu of NO_x as an annual average. The first generation of separated over-fired air registers were installed on Unit 2 in 1998. In 2007, GRE expanded the over-fired air registers on Unit 2 to be low NO_x level 3 ("LNC3," referring to the combination of closed coupled overfired air, separated overfired air, and low NO_x burners). In addition to LNC3, GRE installed and began operating its novel multi-pollutant reduction technology, "DryFining™" in 2010.² Together, the enlarged overfire air registers and DryFining™ technology are combined as "LNC3+" for NO_x reductions.

Black & Veatch is an international engineering firm with vast experience within the power industry. Starting with scrubber designs in the 1960s, Black & Veatch has been involved with 87 air quality control (AQC) projects, with 17 of those related to NO_x control technologies. This includes three NO_x controls-related installations in last five years. Black & Veatch's role on these projects has varied from full engineering, procurement, and construction (EPC) to owner's engineer (OE). Black & Veatch has also provided many engineering services to power clients, including permitting support, risk analyses, and developing BART reports. Since 2006, Black & Veatch has helped numerous clients with fifteen BART analyses, and this does not include many more efforts related to requirements for Maximum Achievable Control Technology (MACT) and Lowest Achievable Emission Rate (LAER).

This report addresses four of the five BART factors: (1) costs of compliance, (2) certain energy and non-air quality environmental impacts of compliance,³ (3) pollution control equipment in use or in existence at the source, and (4) the remaining useful life of the source. 42 U.S.C. § 7491(g)(2). The fifth BART factor, the degree of improvement in visibility which may reasonably be anticipated to result from the use of such technology, *see id.*, will be addressed in a separate report. Black & Veatch identified a number of technologies for NO_x control at Coal Creek Unit 2. A number of these technologies were not carried forward for further analysis because they were not expected to provide substantial NO_x reductions, were not commercially available, or specific circumstances

¹ A BART analysis for NO_x controls at Unit 1 is contained in a separate report.

² As EPA has explained, DryFining™ is an innovative technology developed by GRE that reduces moisture and refines lignite coal, increasing the efficiency and performance of the fuel while reducing emissions. 83 Fed. Reg. 18248, 18251 (Apr. 26, 2018).

³ The impacts to GRE's fly ash reuse program are addressed in a separate report.

preclude their application to Coal Creek Station. Black & Veatch ultimately analyzed selective noncatalytic reduction (SNCR) (with and without multi-level nozzle (MNL) enhancements) and selective catalytic reduction (SCR). SCR was determined to be likely infeasible, but it was analyzed to provide a conservative approach to this report.

Table 1-1 summarizes the cost estimates for the analyzed technologies, which show that none of the technologies are cost-effective. The prior North Dakota BART SIP considered cost effectiveness above \$3,650/ton to be excessive, which was adjusted for inflation to \$4,100/ton in the 2011/2012 NO_x BART determination.⁴ If adjusted to 2018 dollars using the Chemical Engineering Plant Cost Index, this value is \$4,630/ton. The assessed technologies are well above this threshold. In fact, the cost-effectiveness values of the technologies far exceed the values that other states and EPA have determined to be unreasonable in other BART determinations.

Table 1-1 Technology Cost Estimates

TECHNOLOGY	TOTAL CAPITAL INVESTMENT	TOTAL ANNUAL COST (\$/YR)	EFFECTIVENESS (\$/TON NO _x)	INCREMENTAL COST (\$/TON)
SCR	\$190,920,000	\$17,590,000	\$8,737 ⁵	\$8,652
SNCR w/ MNL	\$16,570,000	\$5,970,000	\$8,899	\$4,764
SNCR	\$12,740,000	\$4,860,000	\$11,145	NA

These cost-effectiveness values, along with the other three BART factors addressed in this report (energy and non-air quality environmental impacts, existing controls, and remaining useful life), indicate that none of the considered control technologies are likely to constitute BART.

1.1 REPORT APPROACH

This report follows the methodologies laid out in EPA's BART Guidelines, 40 CFR Part 51, Appendix Y. As described in the BART Guidelines, the first step of the BART analysis is to identify all available retrofit control technologies. These are defined as control technologies with "a practical potential for application to the emission unit." The second step is to eliminate technically infeasible options. A technology must be commercially available and demonstrated at sources under similar operating conditions to be considered technically feasible. The definition of technically feasible is considered the same as an "applicable" technology, per 40 CFR Part 51, Appendix Y. Per this definition, an applicable technology must be commercially available (i.e. it has

⁴ Supporting Material, *North Dakota Supplemental NO_x BART Determination for Coal Creek Station Supplement No. 2 to SIP for Regional Haze* at App. B.2.1, page 16 (Jan. 2, 2013), Docket ID EPA-R08-OAR-2010-0406-0428 (September 2012 Supplemental Evaluation of NO_x BART Determination for CCS 1 and 2).

⁵ The cost-effectiveness value SCR reflects a best-case scenario emission rate of 0.04 lb/MMBtu. For reasons discussed in Section 3.1, the achievable emission rate for Coal Creek Unit 2 is more likely in the range of 0.06-0.08 lb/MMBtu, which would result in even higher cost-effectiveness calculations.

sufficient pilot scale and existing commercial demonstrations to be installed at the facility of interest) and “reasonably be installed and operated on the source type under consideration.” The third step is the evaluation of the controls’ effectiveness, and the fourth step evaluates the impacts (i.e., costs, energy impacts, non-air quality environmental impacts, and remaining useful life) of the remaining control technologies.

This report assesses control costs using two separate methodologies, both of which are consistent with the BART Guidelines and the guidance in EPA’s Air Pollution Control Cost Manual (mentioned from hereon as the Cost Manual). First, this report utilizes EPA’s Cost Manual Excel spreadsheets to calculate the costs of SCR and SNCR. Second, this report also uses, where possible, costs from site-specific vendor quotes and costs based on recent Black & Veatch SCR and SNCR reference projects to provide a more accurate site-specific assessment of these technologies for Coal Creek Unit 2. The reference project costs used in this study come from very recent projects (within 5 years) of similar size (within 150 MW), in similar climates (e.g. severe winters). The line item costs from these projects were compared to the line item requirements for the assessed controls for Coal Creek Unit 2 and were adjusted as necessary (both upward and downward) to account for differences between the projects. As with the vendor quotes, the resulting line item cost estimates are tailored to Unit 2.

Both the BART Guidelines and the Cost Manual explicitly authorize the use of site-specific costs. The BART Guidelines instruct that “[t]he cost analysis should also take into account any site-specific design or other conditions . . . that affect the cost of a particular BART technology option.” 40 CFR Part 50, Appendix Y. Information for this site-specific assessment can come from “additional information” outside the Cost Manual, including information supplied by vendors that affects assumptions regarding purchased equipment costs, equipment life, replacement of major components, or any other element. *See id.*, n.15. As the Cost Manual notes, site-specific vendor quotes are *significantly* more accurate than the “study” estimate provided by the Cost Manual methodology.⁶

EPA has recognized the greater accuracy of site-specific cost estimates in its Regional Haze actions in other Region 8 states. In its partial Federal Implementation Plan (FIP) for Wyoming covering Basin Electric’s Laramie River Unit 1, EPA revised its cost analysis to incorporate site-specific cost estimates provided by Basin Electric, explaining, “Per EPA’s Control Cost Manual (CCM), use of site specific cost estimates is preferable to the use of generalized costs where those site specific costs can be supported and are appropriate.”⁷ Similarly, in its partial FIP for Utah addressing Hunter Unit 1, EPA accepted both the catalyst volume and SCR design suggested by

⁶ Cost Manual, Introduction, Chapter 2, Cost Estimation: Concepts and Methodology, at 6-7.

⁷ *Approval, Disapproval and Promulgation of Implementation Plans; State of Wyoming; Regional Haze State Implementation Plan; Federal Implementation Plan for Regional Haze*, 79 Fed. Reg. 5032, 5039 (Jan. 30, 2014).

Sargent & Lundy for its BART determination.⁸ EPA “acknowledge[d] that States (and EPA in promulgating a FIP) may deviate from the Control Cost Manual provided their analysis is reasonable and the deviations are documented.... Under the BART Guidelines, as explained above, we have the discretion to deviate (or not) from the CCM, so long as our analysis is reasonable and deviations are documented.”⁹ EPA concluded that it “properly [took] into account additional (i.e. outside the CCM) information when it is warranted to use it in our cost estimates, and rejected additional information when it was not warranted to use it in our cost estimates.”¹⁰

1.2 CURRENT CONDITIONS AT COAL CREEK

A major limitation to controlling NO_x is the load variability at Coal Creek Station. Historically, Coal Creek Station has been base-loaded with very infrequent load reductions over 30-day rolling periods. As more renewable resources have become available throughout the upper Midwest, Coal Creek increasingly has been required to reduce load or to vary load in response to these intermittent renewable resources. Coal Creek Station’s units are designed as base load units but are expected to respond more frequently to the transforming mix of renewable generation in MISO.

Coal Creek Unit 2 emitted ~0.13 lb/MMBtu of NO_x as an annual average in 2017 and 2018, with occasional dips down to 0.12 lb/MMBtu as a 24-hour value during optimal conditions and increases to 0.17 lb/MMBtu in poor conditions. Due to coal sodium and load variability, these emission rates can increase. They are lower than what is commonly observed from other coal-fired electric generating units (EGUs) and indicate that Coal Creek Unit 2 has gone through extensive tuning procedures to optimize the combustion process. In a study performed by Alstom Power (now GE)¹¹ in 2015 to comply with the NESHAPs MATS rule, the boiler was found to be well tuned with limited adjustments possible for improving the emissions.

The baseline emission rate of 0.13 lb/MMBtu on an annual average was used for this report’s evaluation of control technologies. Combustion calculations were done using EPRI’s Vista model. Coal information used for the combustion calculations and as part of design considerations/modeling, can be found in Appendix A.

2.0 Initial Technology Screening

There are many available methods to control NO_x emissions but some are not applicable to Coal Creek Station due to their lack of operational experience on units of similar size or operating on similar fuels. It is therefore important to narrow down the list of NO_x control technologies from those that are commercially available to those that are truly applicable for a retrofit installation at Coal Creek Station. Coal Creek Unit 2's baseline of 0.13 lb NO_x/MMBtu, as an annual average, is below the presumptive BART limit of 0.17 lb/MMBtu.¹² Any NO_x reductions must be considered within the context of Coal Creek Unit 2's already low emissions. Some technologies may generally claim NO_x reductions over 40 percent, but these reductions are achieved only when the starting NO_x emissions are much higher than Coal Creek Unit 2's. When the baseline NO_x emissions are low, NO_x removal is more difficult, and reduction capabilities of the technologies will be less. This is important, because a site-specific design is required to fully assess reduction capabilities given the low NO_x baseline. Standard methods based on industry-wide, average data will lead to inaccurate inputs and conclusions. Steps 1 and 2 of the assessment delve deeper into this issue.

2.1 STEP 1 – IDENTIFY NO_x CONTROL TECHNOLOGIES

There are two approaches to achieve a reduction in NO_x emissions: combustion control and post-combustion control. Combustion control methods seek to suppress NO_x formation during the combustion process by controlling the flame temperature and fuel/oxygen ratio. These methods include low NO_x burners (LNBs), overfire air (OFA), and neural network combustion optimization systems. Post-combustion controls use chemical reactions with a reagent to remove NO_x from the flue gas, such as selective non-catalytic reduction (SNCR) and selective catalytic reduction (SCR) systems. SNCR and SCR use either urea or ammonia as a reagent, with the SCR also utilizing catalyst (often multiple layers) to promote the chemical reactions with NO_x.

The first step of a BART analysis is to identify all available retrofit control technologies that potentially could be applied to the facility. NO_x control technologies that were identified as available for retrofit at Coal Creek Station are listed below with a short summary of each technology in the following sub-sections. The listed control technologies meet a minimum level of proven capabilities (e.g., the technologies have been implemented on coal-fired facilities, not just bench and pilot tests). While there may be additional technologies not covered here, their lack of demonstrated performance precludes them from evaluation in this study.

A summary of all identified NO_x control technologies that meet a minimum amount of proven capabilities is provided in Table 2-1.

¹² 40 CFR Part 51, Appendix Y, Section IV.E.5 (Table 1).

TECHNOLOGY	REF SECTION	DESCRIPTION
ECOTUBE	2.2.1	Retractable lances inject air at a high velocity into the furnace above the primary burner zone.
Flue Gas Recirculation (IFGR or FGR)	2.2.2	A portion of the flue gas is extracted downstream of the economizer and re-injected at or near the burner combustion zone or within the existing combustion air ductwork. This location allows for a reduction in excess combustion air, which contributes more nitrogen that can form NO _x . Recirculated flue gas can also lower NO _x formation by lengthening the flame, which reduces maximum flame combustion temperature. This reduction in flame temperature reduces NO _x formation, because NO _x formation is increased at elevated temperatures.
Low NO _x Burners (LNB)	2.2.3	Replace existing LNBS with the most technologically advanced LNBS on the market.
LoTO _x	2.2.4	Injection of ozone to react with NO _x to form N ₂ O ₅ , which is captured by a downstream WFGD.
Natural Gas Reburn	2.2.5	Provide a row of natural gas burners above the primary combustion zone in the furnace to complete combustion, creating CO ₂ with oxygen from the NO _x molecules, reducing NO _x back to elemental N ₂ and O ₂ .
Neural Networks	2.2.6	Optimizing computer controls to maximize NO _x reductions.
NO _x Star™ and NO _x Star Plus™	2.2.7	Ammonia and a hydrocarbon (natural gas) is injected into the flue gas when 1,600 – 1,800° F. The ammonia reduces NO _x and the hydrocarbon reacts with ammonia slip, allowing higher ammonia injection rates.
Overfire Air	2.2.8	Works by reducing the excess air in the primary combustion (burner) zone, which enhances the combustion staging effect and further reduces NO _x emissions. Any residual unburned fuel, such as CO and unburned carbon that escapes the main burner zone, is subsequently oxidized as the OFA is introduced.
Regenerative Selective Catalytic Reduction (RSCR)	2.2.9	Ammonia is injected into the flue gas stream downstream of all air quality control equipment, with a thermal oxidizer and duct burner providing the necessary heat input to allow the catalyst to promote NO _x reduction by ammonia.
ROFA & ROTAMIX	2.2.10	OFA and SNCR combination using a rotating air system to maximize effectiveness.
Selective Catalytic Reduction (SCR)	2.2.11	Ammonia is injected into the flue gas stream upstream of a catalyst, which helps the ammonia reduce NO _x into nitrogen and water. The catalyst is housed in a reactor in the ductwork, usually between the economizer and air heater.

TECHNOLOGY	REF SECTION	DESCRIPTION
Selective Non-Catalytic Reduction (SNCR)	2.2.12	The process involves injecting a urea (H ₂ N - CO - NH ₂) solution at multiple levels in the boiler, where the flue gas temperature ranges from 800 to 1100 °C (1500 to 2000 °F). The urea solution is pumped to the boiler and atomized with compressed air at the injection nozzles.
SNCR/SCR Hybrid	2.2.13	SNCR is used to reduce NO _x from the furnace, and high ammonia slip is used by a single layer of catalyst to further reduce NO _x .

2.2 STEP 2 – ELIMINATE INFEASIBLE NO_x CONTROL OPTIONS

The second step is to eliminate technically infeasible control technologies. This requires determining whether “technical difficulties would preclude the successful use of the control option on the emissions unit under review” based on physical, chemical, or engineering principles. 40 CFR Part 51, Appendix Y, Section IV.D.2.2. Control technologies are technically feasible if either (1) they have been installed and operated successfully for the type of source under review under similar conditions, or (2) the technology could be applied to the source under review. *Id.* For a technology to be capable of being applied, it must be “available” and “applicable.” A technology is considered “available” if the source owner may obtain it through commercial channels, or it is otherwise available within the common sense meaning of the term. An available technology is “applicable” if it can reasonably be installed and operated on the source type under consideration. *Id.* EPA does “not expect a source owner to conduct extended trials to learn how to apply a technology on a total new and dissimilar source type. Consequently, you would not consider technologies in the pilot scale testing stages of development as ‘available’ for purposes of BART review.” *Id.*

The technologies identified in Table 2-1 are explained in greater detail in the subsequent sections. As a result of the analysis in this step, only the technologies that are expected to provide the highest NO_x reductions and are considered technically feasible at Coal Creek Unit 2 are carried forward for further evaluation; technologies with nominal reductions or lack of demonstrations at units similar to Coal Creek Station are eliminated from consideration. Further, two technologies were carried forward despite one being determined to be technically infeasible and the other presenting significant concerns about feasibility, to be conservative in this report’s approach. An overview of the determination to eliminate the technologies is provided in Table 2-2.

Table 2-2 Evaluation to Eliminate Control Options

TECHNOLOGY	BEST ACHIEVED EMISSIONS REDUCTION	EXPECTED EMISSIONS REDUCTION AT UNIT 2	PROVEN ON SIMILAR FACILITIES?	EVALUATION
ECOTUBE	30-90% (per ECOMB)	Not available due to lack of experience	No	Technology not carried forward per discussion in Section 2.2.1

TECHNOLOGY	BEST ACHIEVED EMISSIONS REDUCTION	EXPECTED EMISSIONS REDUCTION AT UNIT 2	PROVEN ON SIMILAR FACILITIES?	EVALUATION
Flue Gas Recirculation (IFGR or FGR)	Up to 40-60% depending on level of FGR	10-15%, depending on level of FGR	Yes	Technology not carried forward due to high maintenance costs seen on previous systems, along with limited space for installation.
Low NO _x Burners (LNB)	Up to 20%	0-5% (system already well tuned with LNBs)	Yes	Technology not carried forward due to currently installed burners being state of the art
LoTOx	30-95+% (per Linde)	Not available due to lack of experience, specifically at large units	No	Technology not carried forward per discussion in Section 2.2.4
Mobotec ROFA & ROTAMIX	Up to 75%	5-23%	No	ROFA is essentially the same as the existing Unit 2 (t-fired system with OFA); ROTAMIX essentially is an SNCR combined with the ROFA system so SNCR is carried forward.
Natural Gas Reburn	Up to 40-60% depending on baseline emissions	10-20%	No	Not carried forward because of lack of natural gas line, natural gas price volatility, limited experience at facilities of 600 MW, and minimal expected reductions at Coal Creek.
Neural Networks	Varied and nominal	0-5%	Yes	Not carried forward due to nominal NO _x reductions.
NO _x Star™ and NO _x Star Plus™	Up to 50%	Not available due to lack of experience	No	Not carried forward due to lack of natural gas line and pilot testing required.
Overfire Air	Up to 40-50%	Already installed	Yes	Currently installed with limited room for improvement
Regenerative Selective Catalytic Reduction (RSCR)	Up to 85%	69%	No	Not carried forward due to lack of experience at units larger than 100 MW
Selective Catalytic Reduction (SCR)	Up to 90%	69%	Yes	Considered for further evaluation, despite feasibility concerns.

TECHNOLOGY	BEST ACHIEVED EMISSIONS REDUCTION	EXPECTED EMISSIONS REDUCTION AT UNIT 2	PROVEN ON SIMILAR FACILITIES?	EVALUATION
Selective Non-Catalytic Reduction (SNCR)	Up to 50%	15-23%	Yes	Considered for further evaluation.
SNCR/SCR Hybrid	Up to 50-60%	33%	Yes	Not carried forward due to technical infeasibility.

2.2.1 ECOTUBE

The ECOTUBE System, by ECOMB, is a boiler combustion improvement and NO_x reduction technology. Retractable lance tubes that penetrate the boiler above the primary burner zone inject high-velocity air as well as reagents. The lance tubes work to create turbulent airflow and to increase the residence time for the air/fuel mixture. In principle, the OFA (see Section 2.2.8) and SNCR (see Section 2.1.12) control strategies are combined in this technology.

The water-cooled ECOTUBES are automatically retracted from the boiler on a regular basis and cleaned to remove layers of soot and other depositions. Additional benefits in terms of furnace combustion are increases in efficiency and reduced fuel usage and corrosion and erosion in the boiler and backend equipment. However, there are no existing installations on boilers of similar type or size as Coal Creek Station. Currently the largest installation is on two 270 MW coal-fired units in France while most of the installations are well under 100 MW and typically at municipal waste or biomass facilities. Scaling the technology up in size from the current largest installation to the size necessary at Coal Creek Station would present risk due to the need for significant technology development and design modifications and would make the system a first-of-its-kind for this size of unit and operation on this type of fuel. Even if ECOTUBE had more apt experience on a unit like Coal Creek Station, the technology combines two technologies that are also evaluated in this report: OFA (which is already installed at Coal Creek Station) and SNCR. For these reasons, ECOTUBE will not be carried forward in this study.

2.2.2 Flue Gas Recirculation

Injection of flue gas into the combustion air, known as Flue Gas Recirculation (FGR), is a proven method for controlling NO_x production from gas-fired utility boilers.

FGR acts to reduce NO_x formation by reducing peak flame temperatures. In conventional applications, the recirculated flue gas is typically extracted from the boiler outlet duct upstream of the air heater. The flue gas is then returned through a separate duct and hot gas fan to the combustion air duct that feeds the windbox. The recirculated flue gas is mixed with the combustion air via air foils or other mixing devices in the duct. At Coal Creek Station this technology would require installation of a separate hot gas fan to move flue gas from the boiler exit to the air supply

ducting at the windbox inlet, where mixing of the air and flue gas must be uniformly achieved by installation of appropriate mixing devices. However, experience has shown that this type of installation requires heavy maintenance due to the particulates in the flue gas eroding equipment as would be present with Falkirk Mine's lignite ash content. It is possible to take flue gas downstream of the particulate control device, but this would require more ductwork, requiring space that is limited around the Coal Creek Station boilers. Furthermore, FGR systems can cause maintenance problems that have led utilities to decommission their FGR systems. For these reasons, FGR will not be carried forward in this study.

2.2.3 Low NO_x Burners

All low NO_x burners (LNB) offered commercially for application to coal-fired boilers control the formation and emission of NO_x through some form of staged combustion. The basic NO_x reduction principles for LNBs are to control and balance the fuel and airflow to each burner, and to control the amount and position of secondary air in the burner zone so that fuel devolatilization and high temperature zones are not oxygen rich. In this process, the mixing of the fuel and the air by the burner is controlled in such a way that ignition and initial combustion of the coal takes place under oxygen deficient conditions, while the mixing of a portion of the combustion air is delayed along the length of the flame.

The objective of this process is to drive the fuel-bound nitrogen out of the coal as quickly as possible, under conditions where no oxygen is present, where it will be forced to form molecular nitrogen, rather than be oxidized to NO_x. Any nitrogen escaping the initial fuel-rich region has a greater opportunity to be converted to NO_x as the combustion process is completed. The net result of staged combustion is usually longer and/or wider flames, due to this delayed mixing process. This is also one of the main reasons why low NO_x combustion is normally associated with the potential for increased carbon in ash and higher CO emissions, as the combustion process begins to encroach on cooled boiler surfaces.

Coal Creek Unit 2 currently uses LNBs. Any additional NO_x reductions that could be achieved by changing burners would vary significantly by burner, as this largely depends on the age and type of LNB. Every major outage, the LNBs are inspected and refurbished, so only nominal upgrades to the existing LNBs are available. Since the Coal Creek Station units are operating at a low NO_x emission rate, substantial reductions in NO_x emissions are not expected from either refurbishing or installing new LNBs, so they will not be carried forward in this study.

2.2.4 LoTOX

The LoTOx technology is the low temperature gas-phase oxidation of NO_x by ozone injection. In this method, ozone is injected into the flue gas upstream of a wet flue gas desulfurization (WFGD) system. The ozone reacts with the NO and NO₂ to form nitrogen pentoxide (N₂O₅). The nitrogen pentoxide formed is soluble in water and can be removed from the flue gas using the WFGD system. The nitrate production (gypsum wash water) from this technology is

captured in the FGD waste product. Most regulatory agencies are very strict about nitrate release into water systems, so Coal Creek Station's evaporation pond would need to be evaluated for potential changes to their chemistry. LoTOx also consumes significant amounts of power, resulting from the multiple ozone generators required to produce the ozone for the process. The power consumption is expected to be comparable to what is needed for a conventional FGD system, which is significantly higher than the power consumption from an SCR.

The LoTOx technology offers high NO_x removal efficiency with a reported potential of 15 to 25 percent savings in capital cost over an SCR with no ammonia slip at small, non-EGU facilities. LoTOx has no commercial installations on coal-fired power plants according to AECOM, the exclusive licensee of the technology. There were some studies of LoTOx on coal-fired power plants in the early parts of the century, but some form of pilot testing would be mandatory before even a cost estimate could be provided for installing LoTOx at Coal Creek Station. Although LoTOx is technically commercially available through AECOM, it will not be carried forward in this study due to its lack of demonstrated performance.

2.2.5 Natural Gas Reburn

The natural gas reburning process employs three separate combustion zones to reduce NO_x emissions. The first zone consists of the normal combustion zone in the lower furnace, which is formed by the existing burners. In this zone, 75 to 80 percent of the total fuel heat input is introduced. The first zone burners are operated with about 10 percent excess air (a 1:10 stoichiometric ratio). A second combustion zone (the reburn zone) is created above the lower furnace by operating a row of conventional natural gas burners at a stoichiometric ratio less than 1.0. This technology also has the potential for increased furnace corrosion (especially with higher sulfur fuels) due to the reducing atmosphere in the lower furnace.

The substoichiometric reburn zone causes NO_x produced in the lower furnace to be reduced to molecular nitrogen and oxygen, because the oxygen stripped from the NO_x molecules is combined with the more active carbon monoxide molecules to form carbon dioxide as combustion is completed in the upper furnace. Fuel burnout is completed in the third zone (the burnout zone) by the introduction of OFA. Sufficient OFA is introduced to complete combustion of the unburned materials in the upper furnace with an overall excess air rate for the boiler of 15 to 20 percent. Reburn technology has demonstrated NO_x reduction of 40 to 65 percent. However, at Coal Creek Station, this is expected to be much less and more on the order of 10 to 20 percent due to the low NO_x baseline.

Sufficient residence time (adequate furnace height) in the reburn and OFA zones is a key factor in determining whether the reburning technology can be applied. Successful retrofit of this technology requires space within the boiler to allow adequate residence time for both the additional burning zone (0.4 to 0.6 second) and the associated OFA burnout zone (0.6 to 0.9 second). When this space is available, reburning can be highly effective, but a low residence time will limit system performance.

Natural gas reburn was part of multiple pilot test programs in the 1990s, and while this led to some permanent installations, many have since been decommissioned or are not operating while still installed. Currently, natural gas reburn installations are scarce, and finding recent performance information about natural gas reburn is difficult, particularly for facilities comparable in size to Coal Creek Station. In Black & Veatch's discussions with other clients over the last several years regarding NO_x controls, natural gas reburn has consistently been averted due to multiple reasons. These include the lack of natural gas at the facility, the volatile price of natural gas, the general inexperience within industry with natural gas reburn, uncertainty on what type of performance could be expected, and expected adverse impacts to overall plant performance.

All of these concerns apply to Coal Creek Station and serve as justification for not carrying natural gas reburn forward as a viable technology. Additionally, GRE currently does not have a supply of natural gas at Coal Creek Station, so a new line would need to be built. As of March 2019, the industry average price for installing natural gas lines is \$1-2 million/mile. There is a current natural gas line that runs parallel to Highway 83, approximately four miles away from the plant. This line would need to be expanded to accommodate delivery of natural gas sufficient for natural gas reburn. If the gas line along Highway 83 is not expanded, then the closest gas lines are currently in Minot (66 miles away) and Bismarck (50 miles away).

Furthermore, concrete evidence is not readily available that natural gas reburn can reduce NO_x emissions by sufficient amounts at a unit the size of Coal Creek Station, especially with its low starting baseline emissions. While natural gas reburn has shown NO_x reductions in excess of 40 percent, the performance is expected to exponentially decline as starting baseline emissions are lowered to the baseline emissions of Coal Creek Station. Overall plant performance will also suffer from installing natural gas reburn, because natural gas burns at lower temperatures than coal, though it is difficult to quantify the decrease in plant efficiency without more data. The lack of industry experience and uncertainties with natural gas reburn disqualifies this technology from further evaluation.

2.2.6 Neural Network Systems

Recent advances in computer hardware and software technology have enabled some power generation facilities to improve their competitive position by implementing cost-effective optimization solutions. This solution, commonly referred to as "boiler optimization" or "neural network systems," provides simultaneous improvements in both plant efficiency and emissions. Neural network computing differs from traditional computing in that engineering, statistical, and first-law principles have been replaced by complex, time varying, nonlinear relationships. Neural network systems use real-time operational data extracted from a plant Distributed Control System (DCS), to "learn" solutions from plant operational experience, and improve plant performance by continuously adapting to changes in plant operation.

Neural network systems also supplement other NO_x reduction strategies. Some of these include LNB, OFA and post-combustion controls such as SCR and SNCR. These systems are also

used to help boiler manufacturers tune boilers with poor combustion characteristics, or after an LNB retrofit or other boiler modifications, such as OFA.

The amount of reduction in NO_x emissions from neural networks is highly dependent on the facility's current operations, as units operating further away from their optimal efficiencies will benefit the most from neural networks. With respect to Coal Creek Station, Unit 2 already has achieved a low NO_x emission rate. As mentioned, Alstom Power (now GE) conducted a study on Unit 2 as part of MATS NO_x/CO optimization, and they concluded that Coal Creek Unit 2 was well tuned. In comparison to other NO_x emission control technologies, neural networks are capable of achieving only minor reductions.

Coal Creek Station has experimented with a few forms of intelligent controls in the past (intelligent soot-blowers and coal-flow algorithm models), both of which did not work and have been since decommissioned in favor of their operators' ability to effectively control the unit. Space is also limited for installing any potential drives for the burners due to the existing layout of the burners in the unit, several of which are nearly adjacent, restricting the scope of a neural network. Considering that neural networks would have a limited, if any, impact on NO_x emissions at Coal Creek Unit 2, and because there is limited physical space for additional installations, they will not be carried forward in this study for Coal Creek Station.

2.2.7 NOXStar™ and NOXStar Plus™

NOXStar™ is the trademarked name for a NO_x control technology that involves the injection of ammonia and a hydrocarbon (typically natural gas) into the flue gas path of a coal-fired boiler at around 1,600 - 1,800° F. The ammonia reduces NO_x through a selective non-catalytic reduction (SNCR) reaction, with the hydrocarbon minimizing the ammonia slip. This enables higher reagent injection rates for NO_x reductions than achievable with a typical SNCR technology.

NOXStar™ eliminates the need for (1) installation of a catalyst reactor and the associated capital costs, (2) economizer modifications, and (3) major outages. By not requiring a catalyst layer the associated problems of chemical poisoning, physical plugging, and sintering due to temperature excursions, pressure drop requiring new ID fans, and disposal of a hazardous solid waste are avoided. The other advantage of the NOXStar™ system is that the conversion of SO₂ to SO₃ is said to be negligible, thus eliminating one of the main drawbacks of the SCR technology.

For installations where the NO_x reduction requirements are greater than can be achieved with NOXStar™, the NOXStar™ Plus system incorporates a single layer of in-duct catalyst into the system. This arrangement is similar to a hybrid SCR/SNCR system with the addition of the hydrocarbon injection to minimize ammonia slip.

The major consideration for the NOXStar™ technology is that it currently has only one major installation in the US on a coal fired unit and may require the installation of a single layer of in-duct catalyst (NOXStar™ Plus) to achieve advertised levels of NO_x reduction. Injecting reagent with lower catalyst volumes resembles an SNCR/SCR hybrid (ASCR), and, as described later, is a technology evaluated later in this report. Extensive research was done in an attempt to obtain

more information on these systems, but an organization representing NOXStar™ in the US has not been identified. Similarly, no performance information has been obtained. In addition, there is currently no supply of supplemental natural gas at the existing plant site.

Information and reports from the original equipment manufacturer (OEM) state that up to 50 percent reduction has been shown with NOXStar™. However, research has been unable to validate these results from any other sources. Therefore, pilot testing would be required to determine what level of NO_x reductions could be achieved at Coal Creek Station. It is expected that due to Coal Creek Station's low baseline emissions, significantly fewer NO_x reductions would be achieved with this technology. Given that pilot testing is needed, NOXStar™ and NOXStar™ Plus will not be carried forward as part of this study for Coal Creek Station.

2.2.8 Overfire Air (OFA) System

OFA works by reducing the excess air in the burner zone, thereby enhancing the combustion staging effect and further reducing NO_x emissions. Any residual unburned material, such as CO and unburned carbon, which inevitably escapes the main burner zone, is subsequently oxidized as the OFA is added.

The performance that can be expected from a given OFA system depends upon a number of factors. As the amount of OFA is increased, the stoichiometry in the burner zone decreases and a point is reached at which CO emissions reach high levels and become uncontrollable. The point at which this occurs can be boiler- and coal-type specific, particularly if a fuel is in anyway difficult to burn, and will also depend upon the extent to which it is possible to balance flows between the individual cyclones or burners. As the OFA amount approaches 10 to 15 percent, the probability for individual burners operating under overall fuel-rich conditions increases, such that pockets of very high CO emissions and unburned carbon will be formed. Similarly, fuel rich operation at burners close to the water walls can begin to lead to local slag formation and increased tube wastage rates, particularly if slagging is an ongoing problem and the coals have a high sulfur content. A fairly high level of unburned material leaving the burner zone can be accommodated by proper overfire port design, where requirements call for rapid and complete mixing of the OFA with the boiler flue gases.

Aggressively staging combustion to reduce NO_x emissions creates a reducing environment in the boiler and can damage the boiler water wall tubes. The reducing environment attacks the iron oxides in the tube metal and can lead to pin holes in the boiler tubes. This phenomenon is referred to as tube wastage. Poor staging in the boiler could lead to tube wastage resulting in an increase in the amount of maintenance and in the worst-case scenario may require a forced outage to repair the tubes.

OFA already exists at Coal Creek Unit 2. Increased circumferential cracking was experienced when the LNC3+ technology was first operated. Adjustments in the flame location and staging of the air in the furnace have reduced excessive circumferential cracking to a certain extent but have not completely eliminated the phenomenon. Operation of an OFA requires an extensive

level of tube repairs in the reduction zone during each major outage. Operators are now better at managing the LNC3+ for low NO_x operations while minimizing slagging and circumferential cracking during baseload operation. As noted elsewhere in this report, coal sodium and load variability can exacerbate slagging and circumferential cracking due to changes in flame location, affecting low NO_x operation.

The expected increase in NO_x removal by optimizing the existing OFA ports is minimal, on the order of less than five (5) percent. Therefore, as a NO_x reduction technology, OFA will not be carried forward in this study for Coal Creek Station.

2.2.9 Regenerative Selective Catalytic Reduction (RSCR)

Babcock Power provides a variation of the typical SCR (see Section 2.2.11), installing the SCR at the tail end of the air quality control (AQC) train, prior to the chimney. Termed as Regenerative Selective Catalytic Reduction (RSCR), the tail end SCRs are typically more costly than high-dust SCR's, mainly because the flue gas needs to be reheated from the FGD exit temperature of approximately 140° F to at least 450° F, and tail end SCRs consume a larger footprint due to a larger SCR box and the heat exchanger. RSCR typically is used for biomass applications where the exhaust gas poisons are too great for a high-dust SCR catalyst.

First, the reagent is injected into the flue gas. The flue gas then passes through a regenerative thermal oxidizer (RTO), which is a large ceramic bed that can absorb and release heat into the flue gas. The flue gas is heated up by the RTO and then passes through the first layer of SCR catalyst. After that, the flue gas passes a duct burner, which provides more heat to the flue gas, and then through the second layer of catalyst. Finally, it passes through another RTO. This time, the flue gas is used to heat up the second RTO. Once the flue gas has used up all the heat in the first RTO, the cycle is reversed, and the second RTO is used as the heat source. This cycle repeats itself again and again, as long as NO_x control is required.

RSCRs generally have much less, if any, impact to the existing ductwork and boiler house structure, whereas the high dust arrangement would require many retrofit modifications. Fewer modifications result in shorter construction and tie-in schedules (e.g. 18-24 months from design to commercial operation of a high dust system, and less than 9 months for tail end). Additionally, less catalyst volume is needed for the tail end application, since the majority of the particulate and SO₂ (including the trace elements that poison the catalyst) have been removed. This also leads to longer catalyst life compared to high dust systems.

One major disadvantage of an RSCR system is an ammonia slip of ~3-4 ppm, which is higher than an SCR. Ammonia slip from an SCR is mostly removed by downstream FGD systems and particulate controls, but that is not the case with an RSCR system that is located immediately before the stack. Any ammonia slip will simply exit the stack as an emission. In addition to the ammonia slip, RSCRs achieve slightly less NO_x removal rates than SCRs (>93 percent for high dust SCR and >85 percent for tail end RSCR), depending on the NO_x baseline. For Coal Creek Station, the NO_x removal rate is expected to be well below 85%, given its low NO_x baseline.

RSCRs have not been installed at coal-fired facilities of Coal Creek Station's size. Babcock Power, the leading vendor of the technology, would not provide a budgetary quote for this effort based on the vendor's determination that this is not a good application for an RSCR. The technology has been installed at many facilities, but the largest to date is only 54 MW. Babcock Power limits the applications to units 100 MW and smaller due to concerns about increasing the reactor sizes. Therefore, while RSCR could be capable of providing NO_x reductions for Coal Creek Station, it will not be carried forward due to an installation at Coal Creek Station being first of a kind for the technology and the unwillingness of the supplier to offer this technology for units of this size.

2.2.10 ROFA and ROTAMIX

AECOM provides a NO_x reduction system that combines LNBs, OFA, and SNCR technologies into an integrated system. The system uses a modified OFA system with mixing characteristics achieved through implementing a rotation to the OFA. This system is called ROFA™ - Rotating Opposed Firing Air. In addition, ROTAMIX™ can be added to the system, which consists of adding urea or ammonia injection into the ROFA™ air nozzles. The extra mixing produced by combining the overfire air nozzles with the reagent injection, results in improved mixing and a more homogeneous temperature profile in the boiler. These technologies were formerly provided by Mobotec but is now currently commercially available through AECOM.

ROFA is effectively a tangential fired boiler with OFA ports. Because Coal Creek Unit 2 is comprised of a tangential fired boiler, meaningful NO_x reductions are not expected from installing ROFA. Furthermore, ROTAMIX is essentially an SNCR with proprietary nozzles and injection system, and as explained later, SNCR is carried forward for further evaluation. Therefore, ROFA and ROTAMIX's benefit to Coal Creek Unit 2 are effectively captured elsewhere in this study. These specific technologies are not carried forward.

2.2.11 Selective Catalytic Reduction (SCR)

2.2.11.1 Technical Background on SCR

SCR systems are the most widely used post-combustion NO_x control technology for achieving significant reductions in NO_x emissions. In SCR systems, vaporized ammonia (NH₃) injected into the flue gas stream acts as a reducing agent. Some large utility boiler SCR installations have been able to lower NO_x emission to rates as low as 0.04 lb/MMBtu, but this is contingent on the unit's operating characteristics. Based on recent data from the Western Regional Air Partnership (WRAP) and EPA's Clean Air Markets Division (CAMD), SCRs on units of similar size as Coal Creek Unit 2 emit NO_x at a rate of 0.05 to 0.08 lb/MMBtu on an annual average.¹³ As will be discussed further in Section 3.1, the vendor quote was based on an emission rate of 0.04 lb/MMBtu, although the emission rate at Coal Creek Unit 2 likely would be higher based on the experience of other similar units.

¹³ Based on information from <http://www.wrapair2.org/EGU.aspx> and <https://ampd.epa.gov/ampd/>.

NO_x and ammonia reagent react to form nitrogen and water vapor. The reaction mechanisms are very efficient with a reagent stoichiometry of approximately 1.05 (on a NO_x reduction basis) with very low ammonia slip (unreacted ammonia emissions). A simplified schematic diagram of a typical SCR reactor is illustrated in Figure 2-1. However, most modern SCR systems are built without a bypass systems and sonic horns are used in place of steam or air sootblowers.

The SCR reactor is the housing for the catalyst. The reactor is basically a widened section of ductwork modified by the addition of gas flow distribution devices, catalyst, catalyst support structures, access doors, and soot blowers. An ammonia injection grid is located upstream of the SCR reactor. The SCR reactor is typically elevated above and behind the air heater, and gas flow direction through the reactor is vertically downward for coal fired applications. There are two types of SCR arrangements: “high-dust” and “low-dust.” In a high-dust SCR arrangement, the reactor is located between the outlet of the economizer and the inlet of the air heater. The high-dust system is typically the most economical and preferred arrangement where physically possible. A low-dust arrangement would locate the SCR after the particulate control device to remove most of the dust from the flue gas stream. This arrangement is preferred when the fly ash contains a high level of catalyst poisons (sodium, arsenic, etc.), and removing most of the fly ash from the flue gas will prolong the catalyst life. Additional discussion of low-dust SCR arrangements in relation to Coal Creek Unit 2 are provided in Appendix B. This report focuses on discussion of high-dust arrangements, as a low-dust arrangement would be even more expensive than a high-dust SCR. Because a high-dust arrangement is determined to be not cost-effective as discussed in Section 4.1.1.2, a low-dust arrangement would be even less cost-effective.

Figure 2-1 Schematic Diagram of Typical SCR Reactor

The ammonia reagent for the SCR systems can be supplied by anhydrous ammonia, aqueous ammonia, or by conversion of urea to ammonia. Since the ammonia is vaporized prior to contact with the catalyst, the selection of ammonia type does not influence the catalyst performance. However, the selection of ammonia type does affect all other subsystem components, including reagent storage, vaporization, injection control, and balance-of-plant requirements. Anhydrous ammonia was assumed for this report, as it is the least expensive and most commonly used reagent.

SCR systems have a variety of interfacing system requirements to support operations. These impacts predominately relate to draft, auxiliary power, soot blowing steam, gas temperature, controls, ductwork, reactor footprint, and air heater. Dependent on arrangement and performance requirements, draft losses can range from 4 to 10 in. w.g. This can be compensated with the addition of ID booster fans. As needed, ductwork, and/or boiler box reinforcement need to be considered. In conjunction with the fan modification, the upgrade of the auxiliary power system might be necessary, which might also be triggered by ammonia supply system requirements.

The major impact of the SCR system can be seen at the air heater where there are two primary areas of concern. One is the formation and deposition of ammonium bisulfate (ABS) on the air heater surface. This will cause an increase in the pressure drop of the air heater and reduced heat transfer, negatively affecting unit efficiency. The other potential danger for the air heater is high concentrations of SO_3 in the flue gas, which increase ahead of the air heater from SCR and SO_2

interactions. Acid gas dewpoint is a function of the acid concentrations (such as SO₃) in the flue gas, so the acid dew point of the flue gas increases after the SCR. This is an important consideration, because the flue gas temperatures significantly decrease after the air heater, potentially below the acid gas dewpoint. During low load operation and in the presence of air leakage, acid gases can condense in the air heater and lead to plugging and corrosion. Several measures can be taken to avoid or correct this situation. Most important is the right composition of the catalyst to minimize the SO₂ to SO₃ conversion rate. Another operational remedy is to change the boiler soot blowing program to shorter cycles. This will reduce the economizer outlet temperature and subsequently the conversion rate of SO₂ to SO₃ downstream of the SCR. Otherwise, modifications to the air heater and downstream equipment, or installation of an SO₃ mitigation system, is required to prevent corrosion.

2.2.11.2 Technical Feasibility of SCR

While SCR is an industry-proven NO_x reduction technology, it has not been proven on units burning North Dakota lignite. There are two primary technical challenges with SCR and North Dakota lignite: catalyst plugging and catalyst fouling. In fact, the North Dakota Department of Health (NDDH) determined in 2009 that high-dust SCRs are not technically feasible for units combusting North Dakota lignite due to these issues.¹⁴ This determination was based heavily on the performance of a high-dust SCR pilot test at a lignite-fired boiler at Coyote Station.¹⁵ There, plugging was observed at the catalyst inlet due to the high levels of alkalis, namely sodium (Na), in the fly ash, which can form alkali sulfates that deactivate catalyst and alkali oxides that physically blind catalyst surfaces.¹⁶ Coal Creek Station would face similar challenges with the sodium content of its lignite coal. As shown in Appendix A, recent samples from the Falkirk Mine show a range of 0-14 percent sodium, approximately 27 percent of the samples are above four percent. While the fly ash analysis from GRE's coal has consistently been under four percent as an annual average, with the average Na₂O weight percent being just above two percent, short term sodium spikes can be expected, increasing the operational risk of SCR catalysts and LNC3+ as discussed in this report.

Given that nearly a decade has passed since the NDDH determination, Black & Veatch conducted additional investigations into the feasibility of SCR at the Coal Creek Station to assess any technological advancements. Black & Veatch contacted three catalyst vendors to provide preliminary guarantees as part of a budgetary quote based on an average coal sodium content of 4 percent. Even at a 4 percent sodium level, one vendor did not provide a budgetary quote. Two vendors provided quotes, one of which requested to remain anonymous.¹⁷ IBIDEN Ceram was the only vendor to provide a formal quote for purposes of the cost analysis in this Report. Their

¹⁴ Best Available Retrofit Technology – Selective Catalytic Reduction, Technical Feasibility Analysis for North Dakota Lignite. Division of Air Quality, ND Department of Health. July/2009.

¹⁶ North Dakota RH SIP, Appendix C.2, Great River Energy, Coal Creek Stations, Units 1 and 2, BART Analysis, Revised December 12, 2007, Document ID EPA-R08-OAR-2010-0406-0006.

¹⁷ Because this vendor requested to remain anonymous, its information cannot be relied upon for purposes of this analysis.

quotation and experience lists are included in Appendix E. IBIDEN Ceram considers the actual sodium range levels of North Dakota lignite (0-14 percent) to be potentially prohibitive and believes they cannot be addressed through catalyst pitch and design, without first performing a pilot test. Pitch refers to the width of the catalyst cell and the wall thickness, so catalysts with smaller pitches are more prone to experience plugging issues. The SCR catalyst used in the study at Coyote Station had a 6 mm pitch, but many current catalysts use a larger pitch. However, the upper end of the North Dakota lignite sodium content range is outside of Ceram's operating experience, and they expect that even a catalyst with a larger pitch would experience an impracticably high deactivation rate as a result of the sodium levels.¹⁸ According to Ceram, because there is no direct experience in the industry with SCR catalyst installed on a unit firing ND lignite, it is difficult to determine with a high level of certainty what the long term impacts will be on the SCR catalyst. A pilot study would confirm the likely deactivation rate, and would require approximately 2,000 to 5,000 hours of operational data.

Ceram suggested that catalyst deactivation concerns could be addressed by the installation of the SCR in a tail-end arrangement (i.e., after all pollution control equipment). Tail-end SCRs, which are a type of low-dust SCR, are more expensive than high dust arrangements due to the need to reheat the flue gas prior to entering the SCR and the potential need to cool the flue gas prior to entering the stack. Flue gas exiting the scrubber is approximately 135° F; for the tail-end SCR to be effective the flue gas needs to be reheated to approximately 500° F. To provide this reheat, a natural gas line would need to be installed to Coal Creek. Additionally, the experience of tail-end SCR applications in the United States is minimal and is limited to small installations. Multiple manufacturers were approached for their experience list. Of these, only Babcock Power has installed tail-end SCR's in the United States, all of them at Oak Creek Power Station units ranging from 261 to 312 MW. Other manufacturers such as GE and Mitsubishi-Hitachi only have installations overseas at unit under 200 MW. Due to this lack of experience, and because the cost a tail-end SCR would be greater than the cost of a high dust SCR, only the high-dust SCR was carried forward for a cost analysis. See Appendix B for further explanation of the additional costs associated with low-dust SCRs, which would include tail-end SCRs.

The concerns about the impact of North Dakota lignite from the Falkirk Mine on the catalyst is shared by Fuel Tech, the vendor of the SCR/SNCR hybrid technology. Fuel Tech has concerns with catalyst erosion associated with the Falkirk Mine coal and would not provide any performance guarantees on the SCR portion of the hybrid technology, even if the sodium content could be guaranteed to remain below four percent, until more is known about the effects of North Dakota lignite ash on catalyst performance and deactivation. Like CERAM, Fuel Tech recommends that pilot scale testing be performed to obtain actual operational data to prove catalyst operation and performance.

¹⁸ A trace element analysis was conducted, and IBIDEN Ceram did not have any concerns with the other poisons' concentrations.

In light of NDDH's prior infeasibility determination, as well as the more recent information obtained by Black & Veatch, plugging and catalyst poisoning likely would render an SCR technically infeasible at Coal Creek Unit 2. Nevertheless, SCR is carried forward to Step 3 in order provide a conservative approach to this BART analysis.¹⁹ In addition, because of the specific technical challenges associated with the installation of SCR at Coal Creek Station, it is critical that a site-specific design be considered when assessing costs.

2.2.12 Selective Non-Catalytic Reduction (SNCR)

Selective Non-Catalytic Reduction (SNCR) systems reduce NO_x emissions by injecting a reagent at multiple levels in the steam generator as illustrated in Figure 2-2. SNCR systems rely solely on reagent injection rather than a catalyst. With respect to reagent injection, there are several critical variables: reagent injection temperature, reagent/gas mixing, and residence time for adequate reaction time to achieve NO_x reductions. SNCR systems can use either ammonia or urea as the reagent. On coal-fired power plants, urea is the predominant reagent of choice. NO_x reactions are delayed when using urea, because the urea must be converted to ammonia. This delay in reaction allows better reagent distribution in the boiler. Urea is injected above the burners and in the upper part of furnace, where the flue gas temperature ranges from 1,500 to 2,200° F. It is important to note that furnace temperatures of a pulverized coal fired boiler can range between 2,500 to 3,000° F. Therefore, the site-specific injection points are critical for maximizing NO_x reductions.

¹⁹ In addition to the concerns about coal sodium levels plugging and/or deactivating the catalyst, there is extremely limited installation space for an SCR. See Section 2.3.1 for further information.

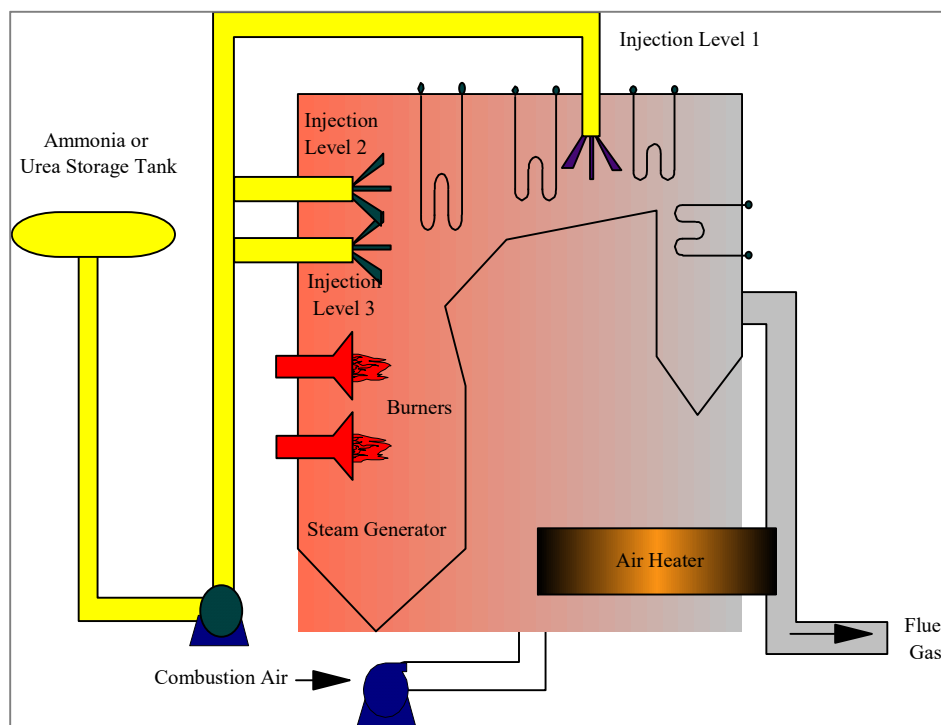

Figure 2-2 Schematic of SNCR System with Multiple Injection Levels

SNCR systems are capable of achieving NO_x emission reductions of 50 to 60 percent in optimum conditions (adequate reaction time, temperature, and reagent/ flue gas mixing, baseline NO_x over 0.35 lb/MMBtu, multiple levels of injectors) with ammonia slip levels ranging from 5 to 50 ppmvd. Lower ammonia slip values are achieved with lower NO_x reduction requirements. Typically, optimum conditions are difficult to consistently achieve, resulting in emission reduction levels of 20 to 40 percent over longer averaging periods. Potential performance is very site-specific and varies with fuel type, steam generator size, allowable ammonia slip, furnace CO concentrations, and steam generator heat transfer characteristics.

SNCR systems reduce NO_x emissions using the same reduction reaction mechanism as SCRs, but without a catalyst. Most of the undesirable chemical reactions occur when reagent is injected at temperatures above or below the optimum range. At best, these undesired reactions consume reagent with no reduction in NO_x emissions while. At worst, the oxidation of ammonia can generate more NO_x. Accordingly, NO_x reductions and overall reaction stoichiometry are very sensitive to the temperature of the flue gas at the reagent injection point. This is particularly complicated for SNCR applications on boilers larger than 100 MW.

Reagent injection lances are usually located between the boiler soot blowers in the pendent superheat section, and installation will require minor modifications to the water walls. Optimum injector location is mainly a function of temperature and residence time. To accommodate SNCR reaction temperature and boiler turndown requirements, multiple levels of injection lances are normally installed. A flue gas residence time of at least 0.3 second in the optimum temperature

range is desired to assure adequate SNCR performance. Residence times in excess of 1 second yield high NO_x reduction levels even under less than ideal mixing conditions.

Computational Fluid Dynamics (CFD) and Chemical Kinetic Modeling (CKM) should be performed to establish the optimum ammonia injection locations and flow patterns for a specific boiler. The EPA Cost Manual Chapter 1, Section 1.2.5 states under Other Considerations under Computational Fluid Dynamics (CFD) and Chemical Kinetic Modeling (CKM), “Each boiler unit has a unique temperature and flow gradient with areas of high flow and stagnation. In addition, temperature and flow profiles vary according to the load capacity under which the boiler is operating. A mathematical model is developed to describe this stratification and variation of important species such as NO_x and SO₃ in the flow stream. To develop the model, the flue gas temperature and velocity within the boiler are measured at many locations. These measurements are used in a CFD model for the convective passes of the boiler. The model predicts the temperature and gas flow within the boiler for various operating conditions and injection scenarios.”

There is limit to overall reductions achievable by SNCR. Per the Institute of Clean Air Companies (ICAC), “As temperature increases, the ‘critical’ or equilibrium NO_x concentration at a given oxygen concentration increases. At high enough temperatures, any reduction of NO_x to below the critical level by SNCR or other means will be counteracted by the rapid oxidation of nitrogen to re-form NO_x. For this reason, at sufficiently high temperatures and baseline NO_x levels below the critical concentration, injection of ammonia or urea into the flue gas will result in increased NO_x levels. If, however, the baseline NO_x concentration is above the critical level, NO_x reduction will result. For typical coal and oil-fired steam boilers, critical NO_x levels are 70-90 ppm (ca. 0.1 lb/MMBtu) in the upper furnace.”²⁰

Coal Creek Unit 2 operates at NO_x emissions near the critical point, as identified by the ICAC, of 0.1 lb/MMBtu. Even though minimal reductions are expected from an SNCR, it is still a well proven technology that can reduce Coal Creek Station’s low NO_x emissions. Therefore, SNCR is determined to be feasible and is carried forward in this analysis.

2.2.13 SNCR/SCR Hybrid

The SNCR/SCR hybrid system uses components and operating characteristics of both SNCR and SCR systems. The result is a NO_x reduction alternative that is lower in capital cost than a full SCR but operating at a higher NO_x reduction than just an SNCR system.

The SNCR component of the hybrid system is identical to the SNCR system described previously, except that the hybrid system may have more levels of multiple lance nozzles for reagent injection. This will increase the capital cost of the SNCR component of the hybrid system. During operation, the SNCR system would be allowed to inject higher amounts of reagent into the flue gas. This increased reagent flow has a twofold effect: NO_x reduction within the boiler is

²⁰ Institute of Clean Air Companies (ICAC). *Selective Non-Catalytic Reduction (SNCR) for controlling NO_x Emissions*. February 2008

increased while ammonia slip also increases. The ammonia that slips from the SNCR is then used as the reagent for the catalyst.

There are two design philosophies for using this excess ammonia slip. The most conservative hybrid systems use the catalyst as an ammonia slip “scrubber” with some nominal NO_x reductions. As with in-duct systems, the flue gas velocity through the catalyst is an important factor in design. Operating ammonia in this mode allows maximum NO_x reduction within the boiler by the SNCR while minimizing the catalyst volume requirement. This results in a relatively cheaper overall installation, but without maximum NO_x reductions. The second philosophy uses a larger catalyst volume, albeit smaller than a full SCR, to obtain greater levels of additional NO_x reduction within the space constraints of the boiler. The additional reduction is a function of the quantity of ammonia slip, catalyst volume, and distribution of ammonia to NO_x within the flue gas.

Fuel Tech is the leading vendor of SNCR/SCR hybrid systems, termed ASCR®.²¹ Fuel Tech has installed a hybrid on multiple coal-fired power plants, including one that is close in size to Coal Creek Station. Fuel Tech assessed Coal Creek Unit 2 and identified concerns with insufficient space available for an ASCR in the boiler building. Due to the existing DryFining™ and reheat systems, there is no room for installation of an ASCR. The system would be required to be installed outside the boiler house, which eliminates the benefits of an ASCR.

Fuel Tech also identified concerns with catalyst erosion associated with North Dakota lignite from the Falkirk Mine. Specifically, Fuel Tech states:

In addition to the spatial limitations, FTEK has several process concerns regarding the sodium (Na) levels in the fuel/ash and sulfur trioxide (SO₃) levels in flue gas. SO₃ in the presence of ammonia (NH₃), in the form of ammonia slip, from the SCR process could lead to ammonium bisulfate plugging in the air heater. Additionally, the SO₃ concentration in the flue gas may convert the Na in the solid phase to a gaseous phase which may cause significant catalyst deactivation. For these reasons, FTEK would not recommend the deployment of the ASCR technology on CCS Unit 2. We would not be willing to provide any performance guarantees on the SCR portion at this time until more is known about the effects of North Dakota lignite ash on catalyst performance and deactivation. FTEK would recommend that pilot scale testing should be performed to obtain actual operational data and learn more about North Dakota lignite and prove catalyst operation and performance.²²

²¹ Fuel Tech is a respected vendor of emission control technology for EGUs. In Region 8 alone, EPA has based final Regional Haze actions in part on data provided by Fuel Tech in Montana, 77 Fed. Reg. 57864, 57885 (Sept. 18, 2012) (relying on Fuel Tech control efficiency estimate); North Dakota, 77 Fed. Reg. 20894, 20897 (Apr. 6, 2012) (relying on SNCR capital costs derived from Fuel Tech budgetary proposal); Utah, 81 Fed. Reg. 43,894, 43,917 (July 5, 2016) (relying on subcontractor report that used Fuel Tech reagent and urea costs); and Wyoming, 79 Fed. Reg. 5032, 5144 (Jan. 30, 2014) (relying on Fuel Tech for utilization factor, urea costs, and emission reduction values).

²² FuelTech Budgetary Quotation; January 21, 2019. Included in Appendix E.

For these reasons, Fuel Tech does not recommend the hybrid technology as feasible at Coal Creek Unit 2. Because the hybrid technology is technically infeasible for Coal Creek Station, it is not carried forward.

3.0 Step 3 – Evaluate Control Effectiveness of Remaining Technologies

For this step of the BART analysis, the SCR and SNCR are evaluated on their effectiveness in removing NO_x. The metric used to determine control effectiveness is lb/MMBtu. This lb/MMBtu metric is eventually converted to a ton/year estimate based upon a projected annual capacity factor. For Coal Creek Station, the annual capacity factor is 87% based on a 10-year average.²³

3.1 SCR

As explained in Section 2.2.11, there are significant site-specific risks that make an SCR infeasible at Coal Creek Station, but the technology is carried forward for further analysis to be conservative. Industry experience has shown that SCRs are capable of achieving NO_x emissions as low as 0.04 lb/MMBtu, with a range of 0.04 to 0.08 on units larger than 550MW. Table 3-1 shows units with SCRs located in Texas and within the WRAP states, along with their annual average emissions.²⁴

Table 3-1 WRAP and Texas Units with SCRs and Emissions⁽¹⁾

DESCRIPTION	COUNT IN DATA SET	ANNUAL AVERAGE EMISSIONS RANGE (LB/MMBTU)
Units with SCR	23	0.039 – 0.08
Units with SCR; > 550 MWg	11	0.039 – 0.08
Units with SCR; > 550 MWg; Burning Lignite	2	0.062 – 0.075
Total Units in Data Set	80 ⁽²⁾	
Notes:		
1. Data obtained from the EPA Acid Rain Database and the Energy Information Administration.		
2. Number does not include units scheduled for retirement.		

Only ten (10) of twenty-three (23) units regularly emit 0.0499 lb/MMBtu NO_x or less on an annual average basis, and none of these nine units burns lignite coal. It is important to highlight that large units with SCRs burning Texas lignite operate at higher emission rates of 0.062 to 0.075 lb/MMBtu as an annual average.

A range of 0.04 to 0.08 lb/MMBtu is assessed in this report based on industry experience at units of similar types and sizes as Coal Creek. Note that some installations at coal fired power plants are capable of reducing NO_x emissions from baseline values by over 90 percent, but the

²³ See Section 1.0.

²⁴ Complete data is available in Appendix F.

percent removal rate expected at Coal Creek Station is lower due to the lower NO_x baseline of 0.13 lb/MMBtu as an annual average.

3.2 SNCR

As an industry leading expert, Fuel Tech was contracted to perform a site-specific assessment for an SNCR's NO_x reductions and associated costs for Coal Creek Unit 2. In October 2018, Fuel Tech mobilized a team to Coal Creek for gathering boiler and emissions data at various loads over a week's worth of tests. These data were then fed into Fuel Tech's proprietary CKM and CFD models to determine site-specific injection locations, urea injection rates, and associated NO_x reductions across the load range of the Coal Creek Unit 2 boiler. The analysis resulted in an estimated reduction percentage of around 15 percent at baseload with a 10ppm slip using a basic SNCR system. Fuel Tech also evaluated an SNCR system using their proprietary multi-nozzle lances (MNL) to obtain better reagent distribution and NO_x reduction. With the MNLs, Fuel Tech estimates a NO_x reduction of 23 percent with a 10ppm slip at baseload.

Fuel Tech's NO_x reduction estimates were lower with an ammonia slip guarantee of 5 ppm (10 and 18 percent with and without MNLs, respectively). Less ammonia injection equals less ammonia slip, which corresponds to lower NO_x reductions. When SNCR vendors attempt to optimize injection, urea is injected in a much more limited fashion, leading to varying ammonia slip rates across the boiler. Due to uncertainty with the varying ammonia concentrations (e.g. stratification across the duct) and how a lower slip greatly restricts an SNCR's performance, Fuel Tech did not provide a 2 ppm ammonia slip guarantee. Table 3-2 shows the ammonia slip and reduction percentages expected with an SNCR. While NO_x reduction percentages would be significantly lower at 2 ppm slip, the rate of decreased NO_x reduction will increase as the ammonia slip decreases (e.g., removal at 2 ppm would be less than 10% when using MNLs).

Table 3-2 Ammonia Slip and Removal Efficiency

AMMONIA SLIP	REMOVAL % WITHOUT MNLS	REMOVAL % WITH MNLS
5 ppm	10	18
10 ppm	15	23

3.3 SUMMARY OF CONTROL EFFECTIVENESS

Table 3-3 summarizes the results of the technologies' control effectiveness.

Table 3-3 Effectiveness of Remaining Control Technologies

TECHNOLOGY	EXPECTED CONTROL EFFICIENCY (%)	EXPECTED GUARANTEED EMISSIONS (LB/MMBTU)
Selective Catalytic Reduction (SCR)	69	0.04
Selective Catalytic Reduction (SCR)	54	0.06
Selective Catalytic Reduction (SCR)	38	0.08
SNCR w/ Multi-Nozzle Lances	23	0.10
Selective Non-Catalytic Reduction (SNCR)	15	0.11

4.0 Step 4 – Evaluate Impacts and Document Results

Per Appendix Y to 40 CFR Part 51, the fourth step of a BART analysis is reviewing the impacts of each control technology in terms of four categories: the cost of compliance, energy impacts, non-air quality environmental impacts, and remaining useful life.

4.1 COST OF COMPLIANCE

Cost estimates for each of the remaining technologies were developed using two separate methodologies for Coal Creek Unit 2.

First, costs for SCR and SNCR were calculated using the EPA Cost Manual spreadsheets.

Second, site specific costs were developed for SCR and SNCR based on budgetary quotes from vendors and cost information from past Black & Veatch projects for similar retrofits. The cost of compliance was based on NO_x baseline emissions of 0.13 lb/MMBtu as an annual average. The tons/year of NO_x removed was calculated from this baseline and the projected annual capacity factor, which is 87 percent based on a 10-year average. Each technology was sized to achieve the highest practical emissions reductions for Coal Creek Station, and sensitivity analyses were run with both SCR and SNCR as discussed below.

The Cost Manual was followed for guidance on what line items to include, as well as sizing and cost estimating calculations for those line items. Again, Black & Veatch used site-specific information from vendors and its own recent SCR and SNCR projects, where appropriate, to make the cost estimates more accurate. Where required, equipment costs were scaled to account for the difference in expected size and performance, based on the on-site inspection of Coal Creek Unit 2 performed by Black & Veatch. Explanations of the cost estimates are provided in the subsections below.

The cost of compliance can be broken down into capital and annual costs. Capital costs generally refer to the money required to design and build the system. This includes direct costs, such as equipment purchases, and installation costs, such as foundations and installation of mechanical equipment. Indirect costs, such as engineering and construction field expenses, are also considered. All of these items sum up to provide the Total Capital Investment (TCI).

Annual costs include the ongoing expenditures to operate and maintain the system. Some noteworthy items are maintenance materials, yearly emissions testing, reagent consumption, utilities consumption (e.g. water and power), and disposal costs.

Table 4-4 and Table 4-5 summarize the costs and effectiveness of each of the technologies.

Table 4-1 Cost of Compliance for Technologies (2018 dollars) Using EPA Spreadsheets

TECHNOLOGY	TOTAL CAPITAL INVESTMENT	TOTAL ANNUAL COST (\$/YR)	EFFECTIVENESS (\$/TON NO _x)
SCR	\$195,655,000	\$16,417,000	\$8,157
SNCR w/ MNL ⁽¹⁾	\$12,534,000	\$4,867,000	\$7,279
SNCR	\$12,179, 000	\$4,833,000	\$11,082

Notes:

1. SNCR w/ MNL cost only changed the removal rate from 15 percent, which is expected from “typical” SNCR systems, and 23 percent, which Fuel Tech expects with their MNL package. Associated costs with the MNL package as described in the site-specific sections are not covered in the EPA spreadsheets.

Table 4-2 Cost of Compliance for Technologies (2018 dollars) Using Site-Specific Approach

TECHNOLOGY	TOTAL CAPITAL INVESTMENT	TOTAL ANNUAL COST (\$/YR)	EFFECTIVENESS (\$/TON NO _x)
SCR ⁽¹⁾	\$190,920,000	\$17,590,000	\$8,737
SNCR w/ MNL	\$16,570,000	\$5,970,000	\$8,899
SNCR	\$12,740,000	\$4,860,000	\$11,145

Notes:

1. The SCR cost is conservatively based on NO_x emissions of 0.04 lb/MMBtu. See Table 4-5 for how the \$/ton changes with different emissions.

4.1.1 SCR

As discussed in Section 2.2.11, costs are assessed for SCR despite the fact that the technology appears infeasible for Coal Creek Station. The costs estimated using two methodological approaches (the EPA Cost Manual spreadsheet methodology and the site-specific methodology) are displayed in Table 4-3.

Table 4-3 Cost of Compliance for SCR Technologies (2018 dollars)

TECHNOLOGY	TOTAL CAPITAL INVESTMENT	TOTAL ANNUAL COST (\$/YR)	EFFECTIVENESS (\$/TON NO _x)
SCR (EPA Spreadsheet)	\$195,655,000	\$16,417,000	\$8,157
SCR (Site-specific Approach)	\$190,920,000	\$17,590,000	\$8,737

Notes:

1. The SCR costs are based on NO_x emissions of 0.04 lb/MMBtu. See Table 4-5 for how the \$/ton changes with different emissions.
2. The EPA Spreadsheet Total Annual Cost and Effectiveness values were developed using the Method 2 calculation which is stated as being applicable to “coal-fired utility boilers” and does not reflect site specific catalyst volumes. The EPA Spreadsheet catalyst volume calculated is approximately half of the site-specific catalyst volume determined necessary by IBIDEN Ceram.

4.1.1.1 EPA Cost Manual Spreadsheet Methodology

The EPA provides a spreadsheet for estimating SCR costs according to the Cost Manual. This spreadsheet uses key site variables such as unit MW, fuel type, NO_x removal rate, and reagent use, and applies the EPA Cost Manual methodology and formulas to these site variables to calculate TCI and total annual costs, which are then used to derive an overall \$/ton cost effectiveness estimate. As shown in Appendix G, Coal Creek Unit 2 variables were added to this spreadsheet. Similar to the site-specific methodology outlined in Section 4.1.1.2, the most restrictive NO_x reduction of 69 percent was used with the spreadsheet based on an annual emission rate of 0.04 lb/MMBtu.

The Cost Manual spreadsheet calculates a TCI of \$195.7 million, and a cost effectiveness of \$8,157/ton NO_x removed, according to 2018 dollars. This value was calculated by using a retrofit factor of 1.0, but the congestion at Coal Creek Unit 2 would justify an increase to the retrofit factor. As observed by Black and Veatch engineers, and as is discussed in more detail below in Section 4.1.1.2, Coal Creek Unit 2's unique DryFining™ and reheat systems occupy the space that typically would be used for installation of an SCR. If the retrofit factor is increased to 1.25 (Cost Manual spreadsheet identifies a range of 1 to 1.5), then the TCI increases to \$244.6 million with a cost effectiveness of \$9,906/ton NO_x removed.

The Total Annual Cost and Cost Effectiveness values were developed using the EPA Spreadsheet Method 2 calculation alternative which does not use site specific catalyst volumes. The spreadsheet does calculate an estimated catalyst volume that is approximately half the amount of the site-specific catalyst volume determined necessary by IBIDEN Ceram. The greater site specific catalyst volume would be expected to result in a higher Total Annual Cost and Effectiveness cost compared to the EPA Spreadsheet default volume.

4.1.1.2 Site-Specific Methodology

A high-dust arrangement was selected for this study's assessment of costs, because low-dust configurations would be more expensive at Coal Creek Station, given the need for both flue gas reheat and cooling, as discussed in Appendix B. If the cost of the high-dust arrangement is deemed to be cost-prohibitive, it is reasonable to assume that a cost analysis for a low-dust arrangement would result in the same conclusion.

The SCR and ancillary equipment were sized based on the most restrictive emission rate of 0.04 lb/MMBtu as an annual average. Catalyst vendors were provided the plant's expected flue gas information downstream of the economizer, based on the ultimate coal analysis of the lignite burned at Coal Creek Station. Trace elemental analysis of the ash at Coal Creek Station was also evaluated for catalyst poisons (sodium, arsenic, etc.). For purposes of this site-specific cost analysis only, IBIDEN Ceram provided a budgetary proposal for their catalyst in a high-dust SCR arrangement, despite their recommendation against a high-dust SCR at Coal Creek Station due to the sodium content of the coal. This proposal assumes a NO_x inlet rate of 0.13 lb/MMBtu (approximately 60 ppm).

The most recent SCR project Black & Veatch has executed was on a 450 MW facility that burns PRB in 2014/2015. Black & Veatch completed an SCR installation in 2009 on a unit similarly sized to Coal Creek Station, but this unit burned an eastern coal that is significantly different from North Dakota lignite. Therefore, the more recent 450 MW SCR project was used as a more appropriate reference case for Coal Creek Station. Escalation factors for differently sized equipment were used, with appropriate parameters used for comparing equipment (e.g. reactor housing was scaled according to the catalyst volume, rather than total flue gas flow rate or units' MW). Inflation from the Chemical Engineering Plant Cost Index (CEPCI) per year was also applied.

Certain items had an elevation factor applied to the costs. The referenced project was at an elevation well over 6,000 feet, and Coal Creek Station is located at 1,940 feet, resulting in a ratio of 0.849. As the atmospheric pressure increases, the volumetric flow rate decreases according to Boyle's Law, so this elevation factor was applied as a cost adjustment where applicable. The Cost Manual uses it as a straight multiplier in some of its equations (e.g., equation 2.41). So, for equipment related to air gas flow, a multiplier of 0.849 was applied.

Table 4-4 provides a summary of the costs for the SCR, with subsequent sections explaining the specific categories of costs used to develop the overall cost estimate. More specific SCR cost information can be found in Appendix C, with the cost sheets provided in Appendix D.

Table 4-4 SCR Cost Summary Using Site-Specific Methodology

CATEGORY	US DOLLARS (2018)
Purchased Equipment Cost (PEC)	\$49,830,000
Direct Installation Cost (DIC)	\$69,130,000
<i>Total Direct Cost (DC = PEC+DIC)</i>	<i>\$118,960,000</i>
Indirect Costs (IC)	\$71,960,000
Total Capital Investment (TCI = DC + IC)	\$190,920,000
Direct Annual Cost (DAC), no ash impacts	\$4,370,000
Indirect Annual Cost (IDAC)	\$13,220,000
Total Annual Cost (TAC = DAC + IDAC)	\$17,590,000
\$/Ton NO_x removed	\$8,737

As discussed in Section 3.1, industry experience has shown that SCRs are capable of achieving NO_x emissions as low as 0.04 lb/MMBtu, with a range of 0.04 to 0.08 on units larger than 550MW. For the purpose of this cost evaluation, the conservative emission rate of 0.04 lb/MMBtu will be used. However, the unique technical risks associated with North Dakota lignite, as described in this document, may drive this emission rate higher to be more consistent with larger installed SCR systems. In particular, large units with SCRs burning Texas lignite operate at higher emission rates of 0.062 to 0.075 lb/MMBtu as an annual average. If the costs for an SCR are assumed to be

the same across NO_x emission rates, the sensitivity of \$/ton according to different NO_x removal rates is provided in Table 4-5.

Table 4-5 SCR Cost with NO_x Emissions Summary (2018 dollars) Using Site-Specific Methodology

NO _x EMISSION	\$/TON
0.04	8,737
0.06	11,233
0.08	15,727

Figure 4-1 shows a general location of where the SCR would be located at Coal Creek Station (ducts and SCR box in red). The general congestion close by the boiler building and elevated construction are evident in the picture. Coal Creek Station installed a novel multipollutant reduction technology ("DryFining™") that processes and dries the lignite prior to combustion. Consequently, the back of the boiler has additional conveyors, processing equipment and DryFining™ baghouses, which are not present on other coal fired units. In addition, Coal Creek Station installed a reheat system in order to run wet scrubbers with a dry stack to meet BART SO₂ limits, as another unique feature, which further restricts available space in the back of the boiler where SCRs are traditionally located. As observed by Black & Veatch engineers, and as illustrated in Figure 4-2, the congestion from these systems preclude installation of an SCR in inside the boiler house. Rather, an SCR installation at Coal Creek Unit 2 must be customized for these unique constraints. Significant parts of DryFining™ and reheat systems would still need to be removed to make space for the SCR ductwork, and then reconfigured for re-installation. As discussed below, this report takes a conservative approach and does not include an estimate of the costs for the reconfiguration.

Figure 4-1 General Sketch of SCR Location

Figure 4-2 Equipment in Boiler Building around ductwork tie-in at Coal Creek Unit 2

4.1.1.2.1 Purchased Equipment Costs

Purchased Equipment Costs (PEC) refers to the cost of purchasing equipment for the SCR from vendors. Significant site-specific costs generally exceeding \$1 million are described below, and explanations of the minor line items can be found in Appendix C. The total PEC for Coal Creek Station's SCR is \$49.83 million.

Figure 4-1 shows a general location of where the SCR would be located at Coal Creek Station (ducts and SCR box in red). The general congestion close by the boiler building and elevated construction are evident in the picture.

- **Reactor Housing** – New steel for the catalyst/reactor housing is required. This does not include new ductwork connecting the reactor to the existing ductwork. The price for this was escalated from the Black & Veatch SCR reference project based on the difference in its catalyst volume and the one provided by IBIDEN Ceram. The catalyst volume was calculated based on the actual volumetric flow rate. Therefore, an elevation adjustment factor was not applied to this cost. Total cost for reactor housing is estimated to be \$3.7 million.
- **Ammonia Injection Grid and Dilution Skid** – An ammonia injection grid is necessary to achieve optimal ammonia injection. A dilution skid is used to help deliver the anhydrous ammonia to the injection grid at a ratio of about 20:1 (air:ammonia). Since the size of the grid corresponds to the size of the reactor, the

difference in catalyst volume was also used to escalate the price. This cost is estimated to be \$2.3 million.

- **Initial Fill of Catalyst** –The catalyst quoted by IBIDEN Ceram is a honeycomb type with a makeup of about 80 percent titanium, 5-10 percent tungsten, and 0-3 percent vanadium. The balance of the catalyst is ceramic material. The volume of catalyst was selected based on having three layers, with a spare layer, and a 24,000 hour life span, consistent with plant outage schedules.²⁵

Based on the coal type and flue gas characteristics IBIDEN Ceram calculated a catalyst volume approximately 2 times greater than the EPA spreadsheet estimate. Coal Creek Unit 2's higher temperature and potential poisons in North Dakota lignite resulted in IBIDEN Ceram calculating a higher volume than a "typical" installation for purposes of this cost assessment, although Ceram expects that this higher volume may be insufficient to address the deactivation rate likely to result from the high sodium levels in North Dakota lignite. This cost is estimated to be \$6.1 million.

- **Ductwork** – The cost of ductwork was escalated from the SCR reference project's costs based on the units' MW, because the ductwork at a coal fired units is reflective of the plant's overall size, not the SCR catalyst volume or ammonia consumption rate. Due to the congestion around the boiler building, the ductwork modifications and additions required to provide flue gas from the economizer to the SCR, and from the SCR to the air pre-heater, are complex. Black & Veatch's reference project used in this cost estimate had much more available space for installing an SCR. Therefore, the pricing was scaled to account for a more congested arrangement as well as difference in sizing requirements. This value is reasonable considering that the location of the SCR in this study is elevated above the ID fans due to limited real estate. There are also potential places beside Coal Creek Unit 2 and on the backside of Coal Creek Unit 1, but since there are complications with ductwork at any of the locations, above the ID fans was chosen. However, offsetting the cost increase from the higher exponent is an adjustment for elevation, or multiplying by the elevation factor of 0.849. This cost is estimated to be \$5.3 million.
- **Air Heater Modifications** – Modifications are necessary to bolster the air preheater from increased SO₃ in the flue gas from the catalyst converting SO₂. Sulfuric acid is more likely to form with increased levels of SO₃, resulting in corrosion problems of downstream equipment like the air preheater. This is particularly a concern with coals with higher sulfur content, as noted by IBIDEN Ceram. Due to the

²⁵ The catalyst costs estimated in this report are conservative. IBIDEN Ceram certifies its catalyst life for 24,000 hours or 36 months from date of delivery, whichever comes first. Because of ordering lead time, catalyst would be stored on-site for several months before installation during the next outage, decreasing the lifespan of that catalyst prior to the mandatory shipment of the next supply. This means that catalyst will be ordered more frequently than the lifespan guarantee, resulting in higher costs than are estimated here.

temperatures exiting the economizer (around 830° F), the catalyst best suited for the flue gas conditions at Coal Creek Unit 2 will oxidize about 5 percent of the SO₂. The flue gas is expected to have around 831 ppm of SO₂. If 5 percent is converted to SO₃, this will result in over 40 ppm of SO₃.

In addition to concerns about air heater corrosion, SO₃ is not readily captured by WFGD systems, resulting in noticeable blue plumes from the stack when the emissions exceed 10 ppm. One solution to the corrosion and blue plume issues is to install an SO₃ mitigation system (often termed SAM, or sulfuric acid mitigation). Current methods of reducing SO₃ in flue gas include injecting a sorbent such as hydrated lime, trona, sodium bicarbonate, or soda ash. Estimating a cost for this type of supplemental system is not part of this study, but based on past projects Black & Veatch would expect a minimum of \$10 million to fully engineer, procure, and construct this system.

The Cost Manual provides an equation (equation 2.43) to estimate the cost of air preheater modifications, and this equation resulted in ~ \$10.5 million.²⁶ Although the Cost Manual contemplates the application of air heater enhancements only for bituminous coal, B&V performed this calculation because of IBIDEN Ceram's concern about the economizer exit temperature and SO₃ creation across the catalyst. Some form of costs associated with increased SO₃ levels should be included, and the Cost Manual's value for air preheater modification was chosen instead of developing costs for a new SAM system.

- **Structural Steel** – In addition to the steel required for the reactor housing and ductwork, support steel must be purchased. This price was scaled up from the reference project based on the units' difference in MW. A significant portion of the steel is related to the ductwork that had an elevation adjustment factor applied to its cost. Therefore, the same adjustment is made to the steel. This cost is estimated to be \$10.6 million.

4.1.1.2.2 Direct Installation Costs (DIC)

The DIC combines with the PEC to give the total direct costs (DC). As its name would imply, direct installation costs (DIC) refer to the costs directly associated with physically installing the SCR. Construction costs are often higher than the PEC, especially for retrofits. Coal Creek Station presents unique retrofit challenges because of existing reheat and DryFinishing™ equipment located on the back of the boiler. Therefore, site-specific design considerations are critical to deriving more accurate cost estimates. A general retrofit factor of some percentage was not universally applied. The following items were included in the DIC – see Appendix D for the values. The DIC was estimated using actual costs from the Black & Veatch reference project, which was also a retrofit.

²⁶ The EPA cost spreadsheet does not include a cost adder for air heater modifications when operating on lignite fuel. When bituminous fuel is selected an air heater modification price of approximately \$10,900,000 is shown.

- **Subsurface Construction** – Prior to installing any foundations or equipment, earth/soil/concrete must be moved along with any underground utility lines. Once this is done, all foundations, piles, ductbank, and embedments can be installed. This price was scaled up from the reference project based on the units' difference in MW. The previous project had more real estate for construction than Coal Creek Station. Therefore, these costs were adjusted by a slightly higher factor of 1.2 to account for physical constraints. This cost is estimated to be \$4.1 and \$1.1 million for earthwork/undergrounds and foundations, respectively.
- **Superstructure Construction** – In addition to the reactor and ductwork, a cost for installing a heated building around the SCR was included. Coal Creek Station experiences temperatures well below freezing, and to accommodate maintenance during the winter months, a heated enclosure is needed. The referenced SCR project by Black & Veatch was also located in an area with harsh winters. Consequently, the price of a heated building was used for this estimate. Since superstructures relate to equipment processing flue gas, the elevation adjustment factor was applied. Similar to the subsurface construction costs, costs were adjusted by factor of 1.2 to account for the congestion differences between the reference project and Coal Creek Station. This cost is estimated to be \$28.4 and \$15.2 million for the reactor/ductwork and the heated building, respectively. A significant portion of this cost is due to multiple large cranes required to build an elevated structure such as the SCR at Coal Creek Station.
- **Demolition and Rebuild** – Space inside and around the boiler building is very congested at Coal Creek Station. It will be extremely difficult to locate SCRs inside the boiler building. Based on Black & Veatch's initial assessment of the facility, including a site inspection and review of applicable engineering drawings, it was determined that, an SCR would have to be elevated and located above the ID fans, requiring more ductwork outside of the boiler house than typical installations. This is accounted for in the line item for ductwork and structural steel.

An additional line item was included to account for the rework inside the boiler house that will be required to tie-in the new ductwork connecting the new SCR to the old ducts. Inside the boiler building, there is a reheat system that takes in ambient air and is heated by the hot duct pantlegs entering the air preheater. As part of the SO₂ BART control strategy, this reheat gas is then directed to the stack, where it mixes with the flue gas leaving the WFGD and raises the overall exhaust gas temperature in order to maintain a dry stack. This reheat system is adjacent to the economizer outlet where SCR ductwork is typically connected. After the SCR duct tie-ins are made, the ductwork needs to exit the boiler building to the new SCR reactor. Due to existing equipment and steel inside the boiler building, the best option is routing the new duct work through the roof. However, GRE's DryFining™ system has ductwork and baghouse equipment in this area. Therefore, rework

would be needed to relocate or demo/rebuild the equipment that is in the way (See Figure 4-1). In brief, the reheat system, heat exchangers, and stacks would be removed in order to create space for installation of the SCR, and then reconfigured for reinstallation²⁷. The removal of these systems would necessitate an outage of approximately 6 to 18 months depending on the final configuration and amount of demolition and relocation required. The cost for this lost revenue would be significant but is not accounted for in this analysis. Access to the SCR could be preserved for the necessary periodic catalyst replacement and other maintenance.

Given the unique congestion issues, site-specific cost estimates must be used for the demolition and rebuild of the reheat or DryFinishing™ ducts. If the reheat section is abandoned, then a wet chimney would be needed. The costs for new stacks are expensive. Based on a past project, a new, wet chimney at Coal Creek Station would cost at least \$16 million. Using past labor rates (manhours and wages) from Black & Veatch projects, the cost to demo and rebuild the reheat ductwork alone is estimated to be \$2.8 million based on the tonnage of Corten steel. This cost did not include the expenses to relocate/reroute significant parts of the DryFinishing™ and reheat equipment, which would require more detailed design work to accomplish. As such, it is viewed as more cost effective to retrofit the reheat duct work. Therefore, the wet chimney option was not incorporated into the cost estimate.

There is a large amount of steel and equipment associated with the DryFinishing™ system. Based on a high-level review of drawings, the cost to demolish and rebuild the DryFinishing™ equipment interfering with the new duct is estimated to be around \$5 million. The costs utilized in this analysis could increase as specific design requirements are analyzed.

- **Mechanical Construction** – This line item deals with installing the mechanical equipment (e.g. pumps, tanks, piping, catalyst layers, etc.). Once the foundations and structures are installed, the mechanical construction costs should be comparable to the referenced project, so the previous project's cost was escalated based on the units' difference in MW. This cost is estimated to be \$6.6 million.
- **Electrical Construction** – This line item deals with installing the electrical equipment. The previous project's cost was escalated based on the units' difference in MW. This cost is estimated to be \$4.4 million.

²⁷ The cost estimate for this study uses a conservative approach by basing re-installation of all equipment in a configuration similar to the current arrangement. It is expected that the re-installation will actually require significant re-design including potentially relocating equipment to a new building outside the existing boiler house.

4.1.1.2.3 Indirect Costs

Indirect costs (IC) refer to those costs associated with executing a project that are not directly attributable to purchased equipment or installation. This includes the following:

- Engineering
- Construction and field expenses²⁸
- Owner's cost
- Startup
- Performance tests
- Contingencies

The Cost Manual does not provide a specific equation for estimating IC. Rather, indirect costs are accounted for in their capital cost equations that comprise the total capital investment. Developing site-specific costs for Coal Creek Station allows the IC values to be explicitly estimated. The costs were calculated as a percentage of the direct costs, based on the reference project's final financials. This cost is estimated to be \$72 million.

4.1.1.2.4 Total Capital Investment

Total Capital Investment (TCI) is the total sum of the DC, IC, and other project costs that must be paid to execute the project. This calculation of TCI does not include Allowable Funds Used During Construction (AFUDC), royalty allowances, preproduction cost, inventory capital, and initial catalyst and chemicals. These costs were provided in the 1998 and 2002 update of the Cost Manual, but then removed from the SCR chapter in the May 2016 update. Since these other costs are no longer part of the Cost Manual, they are not included in this cost analysis.

Using site-specific design information and costs from Black & Veatch's reference project, the TCI was calculated to be \$190,920,000. The reference project used by Black & Veatch in developing this cost estimate was ~450 MW unit, and the total in 2014/2015 dollars was ~\$175 million. The reference project included new ID fans. Some actual indirect and installation costs were unique to the reference project. Considering that Coal Creek Station does not need new ID fans, it saves nearly \$20 million in equipment and installation costs. However, Coal Creek Station is over 30 percent larger with a larger amount of demolition and rebuild required. These differences support the estimated TCI as an appropriate cost estimate. If the costs for DryFinishing™ and reheat systems' demolition and rebuild are excluded, the TCI is \$176,430,000, or very similar to the reference project.

4.1.1.2.5 Direct Annual Costs

Direct annual costs include variable and fixed costs. Fixed annual costs are those that a plant owner will have to pay every year. The Cost Manual assumes that operating labor is 4 hours a day due to the SCR system, which equates to half a full-time employee. An annual salary of \$149,365 was used for this cost estimate based on GRE's cost for operators (based on an hourly

²⁸ Construction and field expenses include costs for crane and scaffolding.

cost of \$71.81/hr). There is also a cost associated with maintenance labor and materials, and the Cost Manual assumes this to be 0.5 percent of the TCI (former editions used 1.5 percent). Black & Veatch included a cost for testing the catalyst activity and fly ash based on past estimates.

In addition to fixed annual costs, variable annual costs exist due to the SCR system. A capacity factor of 0.87 (based on a ten-year average) was provided by GRE and applied to all variable costs. The Cost Manual's Equation 2.58 and 2.59 were used for calculating the cost of reagent consumption and power consumption. The reagent consumption was calculated using a stoichiometric ratio of 1.05, an outlet emission of 0.04 lb/MMBtu, and a 2 ppm ammonia slip. The cost of anhydrous ammonia was provided with delivery included to Bismarck²⁹ by truck. Equations 2.60 and 2.62 were used to calculate the cost from the SCR's power consumption. The cost of power was provided by GRE.

Another variable cost is for replacing catalyst. IBIDEN Ceram's catalyst volume was provided based on a 24,000 hour-lifespan, or three years from the date of delivery, whichever comes first. Coal Creek Unit 2 undergoes a planned major outage every three years, so catalyst replacement may or may not align with this schedule. The plan would be to replace all of the catalyst layers during the major outage. The cost of catalyst was taken from the vendor quote, and a future worth factor (FWF) was applied per the Cost Manual. The FWF "amortizes the catalyst cost over the years preceding the actual catalyst purchase." Since this cost would occur every three years, it was divided by three to determine the annual impact.

For each layer of catalyst that is replaced, the removed catalyst must be properly disposed. Therefore, a disposal cost was applied based on a \$10.50/ton rate provided by GRE. The total DAC is estimated to be \$4.4 million.

4.1.1.2.6 Indirect Annual Costs

Indirect annual costs include administrative costs, property taxes, insurance, overhead, and capital recovery. Insurance and property taxes were assumed to either be nominal or non-existent for the SCR. Overhead was assumed to be negligible since administrative costs comprise a significant portion of overhead costs. Equation 2.69 was used to calculate the administrative costs, and the capital recovery was calculated by the annuity formula based on 5.25 percent interest and a 30-year life. The interest rate was provided by the NDDH (from the EPA), and the 30-year life was taken from the Cost Manual. In general, the capital recovery can be understood as an equal payment over "n" years (in this case 30), so that the current value of the total payments is equivalent to the total capital investment at the specified interest rate. The total IDAC is estimated to be \$13.2 million.

²⁹ The anhydrous ammonia supplier stated that the material would be shipped from Minnesota, so the cost for delivery to Coal Creek Station in lieu of Bismarck is expected to be slightly higher (approximately 50 additional miles). To ensure a conservative estimate, this additional cost is not included.

4.1.1.2.7 SCR Cost Effectiveness Sensitivity

Based on Equation 2.73, the cost effectiveness was calculated by dividing the total annual costs (the sum of direct and indirect costs) by the total tons of NO_x removed per year. The removal rate was based on a conservative outlet emission of 0.04 lb/MMBtu, which as explained in Section 4.1.1, may be higher upon actual installation and operation. The cost effectiveness based on this emission rate is estimated to be \$8,737/ton NO_x removed. The cost effectiveness is estimated to be \$11,233/ton NO_x removed based on an emission rate of 0.06 lb/MMBtu, and \$15,727/ton NO_x removed based on an emission rate of 0.08 lb/MMBtu.

4.1.2 SNCR

Costs were calculated for SNCR using both EPA's cost manual spreadsheet methodology, and a site-specific approach, as summarized in Table 4-6. The high dollar cost per ton of NO_x removed reflects the low baseline NO_x emissions at Coal Creek Unit 2, and the limited additional reductions achievable through SNCR. The unit operates at NO_x emissions near the critical point of 0.1 lb/MMBtu, at which the injection of ammonia or urea will actually result in *increased* NO_x levels.

Table 4-6 Cost of Compliance for SNCR Technologies (2018 dollars)

TECHNOLOGY	TOTAL CAPITAL INVESTMENT	TOTAL ANNUAL COST (\$/YR)	EFFECTIVENESS (\$/TON NO _x)
SNCR w/MNL (EPA Spreadsheet)	\$12,534,000	\$4,867,000	\$7,279
SNCR w/MNL (Site-specific Approach)	\$16,570,000	\$5,970,000	\$8,899
SNCR (EPA Spreadsheet)	\$12,179,000	\$4,833,000	\$11,082
SNCR (Site-specific Approach)	\$12,740,000	\$4,860,000	\$11,145

4.1.2.1 EPA Cost Manual Spreadsheet Methodology

EPA provides a spreadsheet for estimating SNCR costs according to the Cost Manual. This spreadsheet uses key site variables such as baseline NO_x emissions, and normalized stoichiometric ratio (NSR). The spreadsheet applies the EPA Cost Manual Methodology and formulas to these site variables to calculate screening level NO_x reductions and associated TCI and total annual costs, which are then used to derive an overall \$/ton cost effectiveness estimate. As shown in Appendix G, Coal Creek Unit 2 variables were added to this spreadsheet. Similar to the site-specific methodology outlined in Section 4.1.2.2, Fuel Tech's site-specific NSR estimate was used in the spreadsheet calculations. For reasons discussed in this report, the Cost Manual prioritizes the use of vendor-specific NSR calculations where available.

The Cost Manual spreadsheet calculates a TCI for SNCR without MNL of \$12.2 million, and a cost effectiveness of \$11,082/ton NO_x removed, according to 2018 dollars. This value was calculated by using a retrofit factor of 1.0. The Cost Manual spreadsheet calculates a TCI for SNCR with MNL of \$12.5 million, and a cost effectiveness of \$7,279/ton NO_x removed, according to 2018 dollars. This value was calculated by using a retrofit factor of 1.0. The spreadsheet's calculation of MNL cost does not account for site-specific design considerations. Rather, it applies default stoichiometric ratios based on higher MNL percentage removal than would be achieved at CCS Unit 2, resulting in an underestimation of cost effectiveness.

4.1.2.2 Site-Specific Methodology

This analysis provides a vendor-specific estimate by following the Cost Manual's Section 1.3.2 Design Parameters for Detailed/Performance Specifications in Chapter 1 for Selective Non-Catalytic Reduction (SNCR). A detailed analysis was conducted to design and calculate the performance of an SNCR specifically taking into consideration Coal Creek Station's unique boiler over its operational range. As stated in the EPA Pollution Control Cost Manual: "SNCR system design is a proprietary technology. Extensive details of the theory and correlations that can be used to estimate design parameters such as the required NSR are not published in the technical literature. Furthermore, the design is highly site-specific. In light of these complexities, SNCR system design is generally undertaken by providing all of the plant and boiler-specific data to the SNCR system supplier, who specifies the required NSR and other design parameters based on prior experience and computational fluid dynamics and chemical kinetic modeling."³⁰

This report contains cost quotations from Fuel Tech for the design and build of the SNCR system and engineering estimates from Black & Veatch for the installation and construction of the SNCR system. Two system costs were provided by Fuel Tech, one for a system with standard injection lances and another with additional Multiple Nozzle Lances (MNL). The MNL is a proprietary lance designed to provide optimal reagent coverage, particularly at high temperature locations. Fuel Tech estimated that using MNLs along with the standard wall lances provides an 8 percent further reduction in NO_x at baseload. Table 4-7 provides a summary of these two system costs, with descriptions of the costs in following subsections. Refer to Appendix D for details of the individual items' costs. The site-specific cost calculations incorporate the NSR calculated by Fuel Tech.

As stated in the EPA Cost Manual, a system supplier can "more accurately predict the NSR for a given boiler" than the values calculated using the Cost Manuals simplified estimation procedure by accounting for the following factors:³¹

- Reaction temperature range available within the boiler superheater (radiative and convective section) and primary reheater (convective section or cavity) region. If the required temperature window occurs in the radiant section of the boiler, NSR

³⁰ EPA Cost Manual, Chapter 1: Selective Noncatalytic Reduction

³¹ Chapter 1: Selective Noncatalytic Reduction, at 1-39.

could decrease. However, if the temperature window occurs in the convective section, NSR may increase.

- Residence time available in the desirable temperature range. The required NSR decreases as the available residence time increases.
- Degree of mixing between the injected chemical and the flue gases. NSR decreases as the degree of mixing increases.
- Ammonia slip vs. required NO_x reduction. Tighter constraints on ammonia slip would dictate lower NSRs, thereby limiting the achievable NO_x reduction.”

Fuel Tech’s NSR values were developed using proprietary CFD and CKM models that account for Coal Creek Unit 2’s low baseline NO_x emissions among other variables, which are close to the critical NO_x level of 0.1 lb/MMBtu. SNCR needs more reagent as it approaches the critical emissions level, increasing the NSR.

Although Fuel Tech observed NO_x emissions of 0.12 lb/MMBtu and a heat input of 5,971 MMBtu/h during its field testing for the SNCR quote, they confirmed the reduction percentage would be the same for a nominally higher baseline (0.13 lb/MMBtu). Therefore urea usage rates were calculated using the same reduction percentage but based on the baseline value of 0.13 lb/MMBtu of NO_x at a heat input of 6,022 MMBtu/h, which reflect the average conditions at Coal Creek Unit 2.

Table 4-7 SNCR Cost Summary Using Site-Specific Methodology

CATEGORY	US DOLLARS (2018) STANDARD LANCES	US DOLLARS (2018) MULTIPLE NOZZLE LANCE
Purchased Equipment Cost (PEC)	\$3,040,000	\$4,800,000
Direct Installation Cost (DIC)	\$6,690,000	\$7,860,000
<i>Total Direct Cost (DC = PEC+DIC)</i>	<i>\$9,730,000</i>	<i>\$12,660,000</i>
Indirect Costs (IC)	\$3,010,000	\$3,910,000
Total Capital Investment (TCI = DC + IC)	\$12,740,000	\$16,570,000
Direct Annual Cost (DAC), no ash impacts	\$3,820,000	\$4,610,000
Indirect Annual Cost (IDAC)	\$1,040,000	\$1,360,000
Total Annual Cost (TAC = DAC + IDAC)	\$4,860,000	\$5,970,000
\$/Ton NO_x removed	\$11,145	\$8,899

4.1.2.2.1 Purchased Equipment Costs

The PEC primarily consists of the SNCR system that is provided by a supplier/vendor. A budgetary quote from Fuel Tech was used for the PEC, as covering most line items. Costs that were

not covered, such as balance of plant piping and electrical, were included in the installation costs. The total PEC for Coal Creek Unit 2's SNCR was \$3 million with wall injectors only and \$4.8 million with the MNLs.

- **Vendor's Scope of Work** – Fuel Tech was contracted to gather field data and conduct CFD and CKM modeling to develop a budgetary proposal, due to their industry experience and expertise with SNCRs. Other vendor quotes were not solicited. Their quote included a urea storage tank, dilution water skid, injection nozzles, metering equipment, and miscellaneous components.

A 50 percent urea solution was assumed, which would be delivered by truck. An unloading panel is therefore required to transfer the solution from the truck to the holding tank. The trucks have an unloading pump, so the unloading panel solely functions as an indicator of the storage tank level to let the operator know when the truck can be unloaded. The urea storage tanks have a residence time of 30 days. Three storage tanks, each at 70,000 gallons, were included in the proposal from the vendor to meet the 30-day requirement. The storage tank is made of fiber reinforced plastic (FRP), and a typical 14-foot diameter was used for sizing.

Fuel Tech provided two options of injectors for Coal Creek Unit 2; one standard option with three different levels of wall injectors, and another option with the same wall injectors but with additional MNLs. The standard injectors (termed G-1) attach to newly installed ports, and are designed to provide the optimum reagent coverage per the CFD modeling done by Fuel Tech. Zone 1 of the three injection levels also comes with an automatic retract device for the lances in order to protect them when not in use.

The MNL option achieves lower NO_x emissions than the standard wall injectors, because they are designed to provide better reagent coverage. Each MNL has nozzles spaced at various intervals along the whole length of the lance. Cooling water and atomizing air are fed throughout the lance. Each lance can be retracted from the boiler, similar to a soot blower. In addition to extra, larger ports for the MNLs, spools for cooling water are required, increasing the price for the MNL option. The total PEC for Coal Creek Unit 2's SNCR was \$3 million with wall injectors only and \$4.8 million with the MNLs.

4.1.2.2.2 Direct Installation Costs

Various balance of plant items, such as foundations, piping, electrical, were not included in the PEC. These items are included in the direct installation costs similar to the reference SNCR project.

- **Subsurface Construction** – An SNCR system will need some foundational and subsurface work to install major system components, most notably the urea storage tanks. This price was scaled up from the SNCR reference project based on the units' difference in area of the installed equipment, with some reductions due to costs

associated with the reference project's firewater system. No adjustments to the firewater system were included for Coal Creek Station.

The MNLs allow better reagent coverage, so more chemical reactions occur in the flue gas. More reagent can therefore be injected while staying below the ammonia slip requirements, and this higher reagent flow rate results in a higher storage volume. The SNCR with MNLs therefore has a higher subsurface construction cost to account for the additional storage tank capacity. This cost is estimated to be \$1.9 million for the SNCR without MNLs, and \$2.1 million with the MNLs.

- **Superstructure Construction** – Similar to the SCR, an enclosure was provided for major pieces of equipment for the SNCR, such as the storage tanks. This is recommended for operations and maintenance at installations with severe weather conditions, like Coal Creek Station. The reference project was in an environment that endured harsh winters, and likewise had a heated enclosure for major pieces of equipment. No additional ductwork, piers, columns, or other superstructures are needed for an SNCR. Therefore, this line item solely deals with the heated enclosure. The circulation module is provided by Fuel Tech with an enclosure, so the difference in square footage of the remaining modules was used to escalate the costs from the reference project. This cost is estimated to be \$1.4 million, regardless of whether MNLs are included.
- **Mechanical Construction** – This line item deals with the cost of installing all the vendor supplied equipment, as well as procuring and installing balance of plant equipment. The estimated cost was escalated from the reference project based on the units' difference in reagent flow rate. This cost is estimated to be \$2.3 and \$2.8 million without and with the MNLs, respectively.

4.1.2.2.3 Indirect Costs

Indirect costs (IC) refer to those costs associated with executing a project that are not directly attributable to purchased equipment or installation. This includes the following:

- Engineering
- Construction and field expenses
- Owner's cost
- Startup
- Performance tests
- Contingencies

The costs were calculated as a percentage of the direct costs, based on the reference project's final financials. This cost is estimated to be \$3 and \$3.9 million without and with the MNLs, respectively.

4.1.2.2.4 Total Capital Investment

Total Capital Investment (TCI) is the total sum of the DC, IC, and other project costs that must be paid to execute the project. This calculation of TCI does not include Allowable Funds Used During Construction (AFUDC), royalty allowances, preproduction cost, and inventory capital, or initial catalyst and chemicals. These costs were removed from the SNCR chapter of the Cost Manual in the May 2016 update, so they are not included in the overall cost. This cost is estimated to be \$12.7 and \$16.6 million without and with the MNLs, respectively.

4.1.2.2.5 Direct Annual Costs

The direct annual costs for an SNCR were calculated based on the Cost Manual's instructions. The fixed costs included zero additional costs for operating personnel, because the plant's existing operators should be able to incorporate the SNCR's relatively simple system into their current workload. A 1.5 percent cost against the TCI was applied for the annual maintenance and labor costs.

The variable costs for the SNCR were based on a 50 percent reagent solution as-received, with it being diluted to 10 percent prior to injection. The reagent, power, and water consumption rates were taken from the budgetary estimate from Fuel Tech. The reagent cost was provided by Cervantes-Delgado, as-delivered to Bismarck.³² GRE provided the cost of power and water. Equation 1.47 of the Cost Manual was also used to account for additional fuel consumed to vaporize the reagent solution, and the price of coal was provided by GRE. This cost is estimated to be \$3.8 and \$4.6 million without and with the MNLs, respectively.

4.1.2.2.6 Indirect Annual Costs

The indirect annual costs included administrative charges and the cost for capital recovery. The insurance, property taxes, and other indirect costs are assumed to be zero in the Cost Manual, so these costs were not included in this estimate. Equations 1.52 through 1.55 were used to calculate administrative charges and the cost for capital recovery (based on a 5.25 percent interest rate and a 20-year life per the Cost Manual). This cost is estimated to be \$1 and \$1.36 million without and with the MNLs, respectively.

4.1.2.2.7 SNCR Cost Effectiveness

Based on Equation 2.73, the cost effectiveness was calculated by dividing the total annual costs (the sum of direct and indirect costs) by the total tons of NO_x removed per year. The removal rate was based on the removal efficiencies provided by Fuel Tech: a 15% removal rate for the SNCR and a 23% removal rate for the SNCR with the MNLs. The cost effectiveness based on these removal rates are estimated to be \$11,145 and \$8,899 per ton of NO_x removed without and with the MNLs.

³² Cervantes-Delgado stated the urea would be shipped from North Dakota but did not provide an exact location. The differential cost for shipping to Coal Creek Station in lieu of Bismarck is expected to be minor enough as to not impact the calculated direct annual costs.

4.2 COST EFFECTIVENESS

The cost effectiveness of each of the technologies was calculated according to Equation 2.73 of the Cost Manual (SCR section) and 40 CFR 51, Appendix Y, Section IV, D. The cost effectiveness is a value that compares the annualized cost of the technology per ton of pollutant removed. There are two technologies to be considered for cost effectiveness: SCR and SNCR. SNCR was found to be the cheapest option on total annualized costs, but the SCR was the cheapest on a dollar per ton basis when assessed based on tons of NO_x removed.

In addition to the total cost effectiveness, the incremental cost effectiveness was calculated according to 40 CFR 51, Appendix Y. The SNCR annualized cost was used as the basis. The SNCR with MNLs and the SCR were assessed on incremental cost effectiveness from the SNCR basis and adjusted by the difference in TAC and the tons of NO_x removed. Table 4-8 and Table 4-9 shows the average cost effectiveness values in \$(TAC)/ton NO_x removed (per annual basis). Figure 4-3 is a graph of total annualized costs versus emissions reductions. The high cost effectiveness for SNCR is due to Coal Creek's already low NO_x emission rate. Unit 2 is emitting NO_x near the critical value for SNCR systems, where further removal is not possible. This explains why the SNCR's removal capabilities are limited, driving the \$/ton value higher.

As can be seen, the cost effectiveness of all the considered technologies exceeds thresholds determined to be reasonable in other BART determinations, under both calculation methodologies. The North Dakota BART SIP considered cost effectiveness above \$3,650/ton to be excessive, which was adjusted for inflation to \$4,100/ton in the 2011/2012 NO_x BART.³³ If adjusted to 2018 dollars, the NDDH cost effectiveness threshold is approximately \$4,630/ton. The cost-effectiveness of the technologies also exceeds the values that other states and EPA have determined to be unreasonable in other BART determinations, including Nevada, which determined controls to be not cost-effective at \$1,190/ton to \$2,102/ton in 2012.³⁴ Most recently, EPA has proposed to approve Arkansas's determination that controls are not cost-effective at \$5,387/ton to \$5,420/ton. 83 Fed. Reg. 62204, 62220-22 (Nov. 30, 2018).

³⁴ 77 Fed. Reg. 17334 (Mar. 26, 2012) (EPA approval); Nevada Dept. of Env'tl. Prot., Revised Nevada Division of Environmental Protection BART Determination Review of NV Energy's Fort Churchill Generating Station Units 1 and 2, at 5-7 (Oct. 15, 2009), EPA Docket No. EPA-R09-OAR-2011-0130-0004.

Table 4-8 Overall and Incremental Cost Effectiveness (2018 US Dollars) – Using EPA Spreadsheets

TECHNOLOGY	TAC	TON NO _x REMOVED	EFFECTIVENESS (\$/TON NO _x)	INCREMENTAL COST (\$/TON)
SNCR	\$4,833,000	436	\$11,082	--
SNCR w/ MNL	\$4,867,000	669	\$7,279	\$146
SCR ³⁵	\$16,417,000	2,013	\$8,157	\$8,594

Table 4-9 Overall and Incremental Cost Effectiveness (2018 US Dollars) – Site Specific Methodology

TECHNOLOGY	TAC	TON NO _x REMOVED	EFFECTIVENESS (\$/TON NO _x)	INCREMENTAL COST (\$/TON)
SNCR	\$4,860,000	436	\$11,145	--
SNCR w/ MNL	\$5,970,000	669	\$8,899	\$4,764
SCR ³⁶	\$17,590,000	2,012	\$8,737	\$8,652

³⁵ The calculations for SCR are based on an assumed emission rate of 0.04 lb/MMBtu, but as explained in Section 3.1, a range of 0.06-0.08 lb/MMBtu is more reasonable. If the higher emission rates are used, the cost effectiveness of SCR would be even higher.

³⁶ The calculations for SCR are based on an assumed emission rate of 0.04 lb/MMBtu, but as explained in Section 3.1, a range of 0.06-0.08 lb/MMBtu is more reasonable. If the higher emission rates are used, the cost effectiveness of SCR would be even higher.

Figure 4-3 TAC vs Emissions Reduction

4.3 ENERGY AND NON-AIR QUALITY ENVIRONMENTAL IMPACTS

SCR and SNCR have energy and water consumption impacts.³⁷ The energy impacts are primarily related to the auxiliary power consumption of the systems and were included in the cost estimates under the variable annual costs. Similarly, water costs were included as appropriate. Both technologies also would impact GRE's award-winning fly ash reuse program. These impacts

³⁷ All three technologies also would impact GRE's award-winning fly ash reuse program. These impacts are discussed in another report.

are discussed in another report. Please refer to the sheets in Appendix D for further information on the power and water demand of each technology.

4.3.1 SCR

Energy demands from the SCR system are associated the power consumed by the additional pressure drop that the ID fans need to provide, the dilution air blowers, heaters, ammonia pumps, and other minor auxiliary loads. The Cost Manual's equation 2.60 was used for estimating the total power consumption for the SCR, which included increased ID fan loads and resulted in about 3.5 MW.

Ammonia slip will lead to increased nitrogen to the scrubber, which ultimately will be deposited in the evaporation ponds. This nitrogen will act as a nutrient to plants, potentially increasing future pond maintenance requirements and associated costs.

4.3.2 SNCR

For SNCR, power consumption should be nominal, because there is an insignificant impact to the flue gas pressure drop. The urea pumps and dilution skid would be the main power consumers. The power consumption was provided by the SNCR vendor and was listed as 75 and 95 kW with and without MNLs, respectively. Other indirect energy impacts, such as the energy to produce reagents, were not considered in this study.

The SNCR also would consume water as part of the urea injection system, as the urea solution is reduced to 10 percent by weight prior to injection. The water demands are in the mid-100 gpm, which multiplied by an 87 percent capacity factor and 8,760 hours per year, results in about 70 to 80 million gallons per year. This additional water consumption could require an increase in the water appropriations permit.

Ammonia slip will lead to increased nitrogen to the scrubber, which ultimately will be deposited in the evaporation ponds. This nitrogen will act as a nutrient to plants, potentially increasing future pond maintenance requirements and associated costs.

4.4 POLLUTION CONTROL EQUIPMENT IN USE/EXISTING AT THE SOURCE

Coal Creek Unit 2 already has existing NO_x controls in place that have yielded a low NO_x emissions baseline. The facility uses LNBs, DryFining™, OFA, and tuning to achieve this low emission rate. DryFining™, in particular, is a unique technology developed by GRE that reduces moisture and refines lignite coal, increasing the efficiency and performance of the fuel while reducing emissions.³⁸ Coal Creek Unit 2 employs an electrostatic precipitator (ESP) for collecting particulate matter such as fly ash. After the ESP, flue gas passes through a wet flue gas desulfurization (WFGD) system that removes acid gas from the system.

³⁸ 83 Fed. Reg. 18248, 18251 (Apr. 26, 2018).

Coal Creek Unit 2 has a higher economizer temperature than many installations, and this elevated temperature will result in more SO₂/SO₃ conversion across an SCR catalyst. Modifications due to SO₃ are discussed further in Section 2.2.11, most notably the air heater.

The WFGD's acid removal should not be adversely affected. Ammonia can act as a base or acid, and it will be absorbed in the WFGD solute. At the low concentrations of ammonia slip the technologies are designed for, ammonia should not adversely affect the solution's pH or chemistry.

4.5 REMAINING USEFUL LIFE OF ANY POTENTIALLY AFFECTED SOURCES

Consistent with GRE's resource plan, Coal Creek Station will continue to operate for at least 30 years. The facility is well managed and operated. Further, long term investments have been made in the plant (e.g. DryFinishing™ and HVDC converter replacements). Therefore, the lifetimes of the evaluated technologies were kept at the Cost Manual's values (30 years for SCR and 20 for SNCR), as opposed to lesser values based on a limited forecast of Coal Creek Unit 2's life.

5.0 Conclusion

The specific challenges associated with the combustion of North Dakota lignite, as well as the extremely limited space for the installation of controls in the boiler house, significantly limit the feasibility of NO_x controls on Coal Creek Unit 2. There are significant concerns about the technical feasibility of SCR but the technology was carried forward for further review, along with SNCR, in order to provide a conservative approach to this BART analysis.

This further review revealed that neither of the controls are cost-effective, regardless of the cost assessment methodology employed. SCR and SNCR (both with and without MNL) far exceed the \$4,630/ton threshold (adjusted for inflation) that has been applied by NDDH in past BART determinations, as well as exceeding the values determined by other states and EPA to be unreasonable. These high cost-effectiveness values were calculated using both site-specific cost assessments and EPA's spreadsheet methodology. The high values reflect the low NO_x emission rate of 0.13 lb/MMBtu, as an annual average, already achieved at Coal Creek Unit 2 through the implementation of LNC3+. This low NO_x baseline limits the availability of further NO_x reductions. For example, SNCR would achieve minimal reductions, as the facility operates near the critical point of 0.1 lb/MMBtu, after which the injection of ammonia or urea actually results in *increased* NO_x emissions. In light of these cost effectiveness values, as well the low NO_x baseline and the energy and non-air environmental impacts of the considered controls, none of the three technologies are determined to be BART.

³⁹ Nitrogen Oxide and Nitrogen Dioxide values shown are the VISTA model output values used to calculate the initial NOx emission rate of 126 ppm provided to IBIDEN Ceram in October 2018. Following this initial communication, the actual Unit 2 emission rate of 60 ppm was provided to IBIDEN Ceram. IBIDEN Ceram confirmed they are able to achieve 69% reduction for both inlet NOx values of 126 ppm and 60 ppm, as Case 1 and Case 2 respectively, (see quotation in Appendix D).

A.4 FALKIRK PIT SAMPLES – 20 YEAR PROJECTION

Appendix B. Technical Discussion of Low-Dust SCR

Although this BART analysis assesses high-dust SCR, low-dust SCR also was initially considered. Low-dust SCR was not assessed further because it would be more expensive than a high-dust SCR. Since a high-dust SCR was determined to be not cost-effective, there was no need to conduct a cost analysis for a low-dust SCR. The high costs of low-dust SCR are driven by two factors: (1) heating and cooling requirements, and (2) the potential need for a natural gas line. These factors would increase the costs of SCR *above* the high-dust SCR costs already assessed in the body of this report.

First, Coal Creek Station would be required to install a system for reheating the flue gas before it passes through the low-dust SCR, as well as a system for cooling down the flue gas after the SCR. The low dust arrangement is commonly installed after the air preheater, resulting in temperatures in the mid-300s°F, which is too low for a catalyst to work. Thus, the inlet temperature to the low-dust SCR must be increased. The flue gas temperature must then be reduced after passing through the low-dust SCR to accommodate the wet flue gas desulfurization (WFGD) system at Coal Creek Unit 2. There is very little temperature drop across the SCR, so flue gas leaving the SCR would be near 600° F. The WFGD is not designed with sufficient spray capacity to lower incoming flue gas from 600° F to its operating conditions. The WFGD mist eliminators are designed to 300° F, but the flue gas temperature would need to be dropped well below this due to performance considerations. The absorber vessels typically operate with the flue gas at 11 ft/s, and the plant operates to maintain the velocity below 18 ft/s to prevent carryover. As the flue gas temperature increases, the volume and velocity increase. Elevated temperatures and increased velocities will also have an adverse impact on the SO₂ removal percentage. Accordingly, the SCR outlet temperature would have to be lowered for the WFGD to operate as designed.

There are multiple ways to accomplish the cooling and heating methods, and two were examined as part of this study. The first method would be to install heating equipment that uses combustion for adding heat, such as a thermal oxidizer, and then a cooling system that uses some form of external heat reject to exchange heat with the flue gas, such as a fluid system (e.g. glycol or Dowtherm A) with coils inside the duct and fin fans outside. Based on a 2007 estimate for a thermal oxidizer and applying the general 6/10 rule of escalation for volume and temperature differences and a 3 percent inflation rate, a general equipment cost of \$1.43 million was calculated. Additional BOP equipment (e.g. structural steel) would be required, so a high-level factor of 2x can be used for the BOP equipment. Applying a 2x factor for installation then a high-level cost of \$5.7 million is obtained for the heater section. The cooling section is more complicated, as determining costs would require piping lengths, fans, coolant, etc. Glycol is not suitable for the temperature ranges, so Dowtherm A was identified as a heat exchange fluid. Using past quotes for air cooled heat exchangers and a budgetary quote from Dow Chemical, a cooling system was estimated to cost \$11.3 million. This includes a 2x factor for installation. Due to uncertainty with piping, this price

could be higher upon implementation. Combined with the heater, the total cost for this option is about \$17 million.

The second method would be using a gas/gas heat exchanger, similar to an air preheater. At a high level, Ljungstrom style of gas/gas heat exchangers (2x50 percent) would cost about \$17.1 million to install. This cost will likely be higher due to additional ductwork that needs to be installed, but without doing detailed engineering, a precise cost estimate cannot be determined.

If the selected heating system relies upon natural gas, there would be significant additional costs. Coal Creek Station does not have a natural gas line to supply natural gas burners, so one would need to be constructed. Generally, it costs about \$1-2 million per mile of installed natural gas line, as discussed in Section 2.2.5.

Appendix C. Discussions of Minor Line Items in Cost Estimates

C.1 SCR

C.1.1 Purchased Equipment Costs

- **Anhydrous Ammonia Tank** – This is based on 30 days of storage capacity. Due to the severe winter conditions and remote location of Coal Creek Station, 30 days of capacity is needed to provide ample reserves in case of road closures. This time frame was provided by GRE. The cost from the reference project's anhydrous ammonia tank was scaled down based on the tank's capacity.
- **Air Compressors** – GRE has stated that the existing air compressor system was recently upgraded, with a new, fourth compressor having been installed. New compressors were assumed not to be needed, but the cost of two new compressed air receivers (2 x 100%) were included. By not requiring new air compressors approximately \$150k was avoided in PEC.
- **Vaporizers** – Anhydrous ammonia is fully vaporized before being delivered to the dilution skid. The price of a vaporizer skid from the reference project was scaled down according to the differences in ammonia consumption rates.
- **Ammonia Unloading Skids** – Ammonia is assumed to come by trucks, so a method of unloading the ammonia and transferring it to the storage tank is required. The price from the reference SCR project was used without any scaling, because the number of deliveries and size of trucks were expected to be similar.
- **Ammonia Supply Pump Skid** – Pumps are required to feed the ammonia to the SCR, and the reference project's price was scaled down according to the differences in ammonia consumption rates.
- **Miscellaneous Ammonia Handling and Injection Equipment** – This line item includes general miscellaneous items not covered above, such as piping, a mixing chamber, etc. The overall cost of all purchased equipment for the ammonia handling and injection contract, minus the equipment specifically identified, was used for this cost and adjusted based on the difference in MW between Coal Creek Station and the referenced project. The ammonia consumption rate was not used, because the amount of miscellaneous equipment is more related to the overall size of the units. Piping for example will have larger spans to traverse on a larger boiler, so even if the ammonia consumption rate is lower, the total piping material will be more.

- **Ash Handling Modifications** – Fly ash will separate out from the flue gas stream as it passes through the SCR reactor and catalyst layers. The fly ash is collected in a hopper at the bottom of the SCR, and this needs to be connected to the existing fly ash system. The cost for this was scaled from the reference project's costs based on the units' size difference in MW.
- **Electrical Equipment** – This covers the costs for electrical equipment (e.g. transformers, cabling, etc.) that are required for an SCR. This price was scaled up from the reference project based on the units' difference in MW.
- **Induced Draft or Booster Fans** – No costs were included for new ID fans or booster fans. Black & Veatch's reference project installed new ID fans, and if those costs are applied to Unit 2, nearly 20 million dollars (including installation) would have been added to the overall capital cost. The pressure drop across the catalyst layers is expected to be anywhere from 2.1 to 2.60 inches w.g. (according to IBDIEN Ceram), and including the ductwork, LPA screen, and mixing devices, over 6 inches w.g. of pressure drop can be expected. Coal Creek Unit 2 has four, identical ID fans with VFDs, and all of them normally operate at a speed around 640 rpm. The fan curve shows that at 705 rpm, the fans provide about 19 inches w.g. of pressure rise, and at 880 rpm, the fans provide about 37.5 inches of pressure rise. These readings are taken at 2.1 million lb/h of flue gas, which was calculated from the results of a stack test in 2017, here near 8.4 million lb/h of flue gas was measured. Considering where the fans are currently operating, there is enough margin available in the fans' capabilities to overcome the pressure losses from a new SCR.
- **Sonic Horns** – There are two traditional ways of cleaning SCR catalysts from various deposits that can plug up catalyst, soot blowing and sonic horns. Both have been shown to work, but prices for sonic horns were readily available when developing the cost estimates for this report. Therefore, sonic horns were used in the cost estimate. A change to soot blowers would not significantly increase the overall SCR price. An elevation adjustment factor was applied after escalating the cost from the reference facility based on MW.
- **LPA Screens** – A screen is placed upstream of the SCR catalyst to collect large particle ash (LPA). This price was scaled up based on the units' difference in catalyst volume, and the cost was adjusted according to the elevation.
- **Flow Modeling** – Physical models at 1/12 of the actual scale are often used when designing and building an SCR, because CFD models often are not precise in predicting ash flow patterns. The price from the reference project was used without any adjustment, because the price difference is expected to be nominal.

- **Instruments and Controls** – As with any system, instrumentation will be needed to provide process data for operators. SCRs do not require as much instrumentation as other control systems, like a flue gas desulfurization (FGD) system, but costs for additional instruments are required. Based on the reference project, a general 2 percent of the total capital costs is applied.
- **NO_x Monitoring** – NO_x analyzers and associated equipment are provided as a process control. This is separate from a continuous emissions monitoring system (CEMS), as there is already a NO_x CEMS at Coal Creek Station. The price from the reference project was used without any adjustment, because the cost of analyzers and the associated equipment should be nearly constant. This cost is estimated to be \$1.3 million.
- **Taxes and Freight** – A general 7 percent tax (confirmed by GRE) and 5 percent freight charge are applied against the total capital costs. These numbers can fluctuate, but neither will have a significant impact on the overall price. This cost is estimated to be \$3 and \$2.2 million for taxes and freight, respectively.

C.1.2 Direct Installation Costs

- **Spare Parts, Training, Technical Assistance** – When installing a system, it is routine to have a set number of spare parts in the warehouse for startup and for turning over to the owner. Training and technical assistance from vendors is also necessary to properly install and startup the equipment. The previous project's cost was escalated based on the units' difference in MW.

C.2 SNCR

C.2.1 Purchased Equipment Costs

- **Vendor's Scope of Work** – Solutions such as urea must be continuously agitated to ensure the solids stay in solution, so a circulation module was included in Fuel Tech's quote. The circulation module includes two pumps and a strainer, with appropriate instrumentation, connected to the storage tank and metering module. Due to the cold temperatures at Coal Creek Station, a weather enclosure for the circulation module was included by Fuel Tech.

Prior to being injected into the furnace, the urea solution is diluted with water (to 10 percent in Fuel Tech's design), which is provided by the plant. Fuel Tech has provided a strainer/pump system to account for the SNCR's pressure and flow requirements. In addition to the dilution module, a metering module is in Fuel Tech's scope of supply. The metering module regulates the flow and pressure of diluted solution to each injection zone, and due to its criticality, some form of weather protection is necessary. This was not included in Fuel Tech's scope of

supply though, but rather it is in the Balance of Plant's scope, described in the subsection below.

After the metering modules, distribution modules mix the reagent with atomizing air. Compressed instrument air was assumed to be provided by the plant, because there is sufficient capacity in the existing compressed air system. The distribution modules are located near the injectors.

- **Air Compressors** – A cost for two receivers was included in the cost estimate. Coal Creek Station's instrument air system has sufficient capacity. By not requiring new air compressors approximately \$150k was avoided in PEC.
- **Monitoring Equipment** – The existing CEMS may be used for monitoring but to minimize ammonia consumption, individual monitors will be required in each furnace. The monitors will provide the necessary process control to allow operational control of each furnace, minimizing ammonia costs. The value included for the monitors was minimal and has no significant impact on the total project cost.
- **Taxes and Freight** – A general 7 percent tax (confirmed by GRE) and 5 percent freight charge are applied against the total capital costs. These numbers can fluctuate, but neither will have a significant impact on the overall price.

C.2.2 Direct Installation Costs

- **Electrical Construction** – This line item deals with installing the electrical equipment. The previous project's cost was escalated based on the units' difference in reagent flow rate.
- **Boiler Modifications** – New ports for the injection lances will be required, so new boiler penetrations will be needed. Babcock Power was contacted to obtain a general, high level cost for providing seal boxes and penetrations to be installed on site by GRE. GRE's labor costs and past experience, on the time required to install boiler penetrations, were used to calculate a general cost for the new ports. This is higher for the system with MNLs, because the MNLs are additional penetrations that are larger than traditional wall injectors.
- **Spare Parts, Training, Technical Assistance** – When installing a system, it is routine to have a set number of spare parts in the warehouse for startup and for turning over to the owner. Training and technical assistance from vendors is also necessary to properly install and startup the equipment. The previous project's cost was escalated based on the units' difference in reagent flow rate.

Appendix D. Site Specific Cost Estimate Summary Sheets

GRE Coal Creek - Cost Analysis

Technology: Selective Catalytic ReductionDate: 3/4/2019

Cost Item	2018 \$	Remarks/Cost Basis		
CAPITAL COST				
Direct Costs				
Purchased equipment costs				
Reactor housing	\$3,690,000			Engineering estimate based on past project
Ammonia handling and injection				
Ammonia Injection Grid & dilution skid	\$2,260,000			Engineering estimate based on past project
Anhydrous ammonia tank	\$520,000			Engineering estimate based on past project
Air Compressors (plant's existing has spare capacity)	\$20,000			Plant's existing compressor have spare capacity, receivers only
Vaporizers	\$380,000			Engineering estimate based on past project
Ammonia unloading skids	\$530,000			Engineering estimate based on past project
Ammonia supply pump skid	\$200,000			Engineering estimate based on past project
Miscellaneous equipment/components	\$160,000			Engineering estimate based on past project
Mixing Chamber (included)	---			Included as part of the dilution skid
Piping (ammonia supply, etc)	---			Included in Mechanical Construction
Initial catalyst (Ceram)	\$6,100,000			Quote from catalyst supplier
Flue gas handling: ductwork	\$5,270,000			Engineering estimate based on past project
Air heater modifications	\$10,500,000			Per Cost Manual Equation 2.43
ASH handling (e.g. conveyors)	\$670,000			Engineering estimate based on past project
Electrical equipment	\$250,000			Engineering estimate based on past project
Structural steel	\$10,600,000			Engineering estimate based on past project
ID Fan (no upgrade or new required)	---			Fan curves indicate sufficient capacity for additional pressure drop
Misc. equipment				
Sonic horns	\$290,000			Engineering estimate based on past project
LPA screens / rappers	\$760,000			Engineering estimate based on past project
NOx/NH3 monitoring	\$1,340,000			Engineering estimate based on past project Added \$20k for another monitor without emit
Flow modeling	\$190,000			Engineering estimate based on past project
Subtotal capital cost (CC)	\$43,710,000			
Instruments and controls	\$870,000	(CC) X	2.0%	
Taxes	\$3,060,000	(CC) X	7.0%	
Freight	\$2,190,000	(CC) X	5.0%	
Total purchased equipment cost (PEC)	\$49,830,000			
Direct installation costs				
Subsurface construction				
Earthwork, underground utilities, etc.	\$4,070,000			Engineering estimate based on past project
Foundations (including embedments)	\$1,120,000			Engineering estimate based on past project
Superstructures construction				
Reactor housing, ductwork, etc.	\$28,380,000			Engineering estimate based on past project
Heated building	\$15,230,000			Engineering estimate based on past project
Demo and Rebuild	\$9,030,000			
Mechanical construction	\$6,600,000			Engineering estimate based on past project
Electrical construction	\$4,350,000			Engineering estimate based on past project
Spare parts, training, TA	\$350,000			Engineering estimate based on past project
