## **INTRODUCTION**

North Dakota Administrative Code (NDAC) Section 33.1-16-02.1-02 states that it is public policy to protect and maintain all waters of the state, including groundwater. In North Dakota, nearly 75 percent of public water systems utilize groundwater as the source of their water supplies. The North Dakota Department of Environmental Quality (NDDEQ) Groundwater Protection Program's mission is to ensure that North Dakota's groundwater supply remains safe for public use.

The Groundwater Protection Program includes several sub-programs: the Agricultural Ambient Groundwater Monitoring Program (AAMP), the Western Ambient Groundwater Monitoring Program (WAMP), the Underground Injection Control (UIC) Program, and the Source Water Protection Program (SWPP). Together, these four programs protect groundwater through active monitoring, control of contamination sources, and public engagement in groundwater protection.

As of July 2016, the North Dakota State Water Commission (SWC) had defined and named more than 200 shallow glacial drift aquifers within North Dakota, encompassing more than 11,000 square miles ( $\text{mi}^2$ ) (Attachment 3). A method of assessing an aquifer's pollution potential and monitoring priority is vital to ensuring that state resources are efficiently utilized. In 1997, the NDDoH developed the North Dakota Geographic Targeting System for Groundwater Monitoring (GTS) to accomplish this task.

The purpose of the 1997 GTS was to ensure that monitoring efforts be focused on the highest priority aquifers (Radig, 1997). To accomplish this, the GTS utilized a three-component system that produced an ordinal ranking of aquifer monitoring priority. The three components defined by the GTS were Vulnerability, Sensitivity, and Risk. Each component carried an equal weight, was assigned a score between 1 and 3, and was then combined with other components to produce a final monitoring score ranging from 3 to 9. The aquifer was then designated as Low Priority (final score of 3-4), Moderate Priority (5-7), or High Priority (8-9). This ranking and some of the intermediate outputs of the GTS were then used to design aquifer monitoring plans, designate sensitive groundwater areas, and develop the generic State Management Plan for Pesticides.

Since the completion of the GTS in 1997, North Dakota has experienced an increase in oil and gas development, increased agricultural production, and an increase in population (U.S. Census Bureau, 2016). Additionally, in the early 2000s, the SWC began to reassess aquifer boundaries, which significantly changed the regulatory geography of North Dakota's groundwater resources. In the face of so much social and economic change, it is necessary to reassess monitoring priorities to ensure that state resources continue to be used most efficiently. Consequently, this new iteration of the GTS was completed to reassess monitoring priorities for existing glacial drift aquifers, assign monitoring priorities to new aquifers, and update the methods of the GTS to include new geographic information system (GIS) capabilities.

## GOAL

The goal of the 2019 GTS was to reassess monitoring priorities for existing glacial drift aquifers, assign monitoring priorities to new aquifers, and update the methods of the GTS to include new geographic information system (GIS) capabilities.

## PROJECT DESIGN

The 2019 GTS followed the three-component system established by the 1997 GTS. These components — Vulnerability, Sensitivity, and Risk — were used to generate a composite monitoring score. Data was collected from existing sources such as borehole logs, county groundwater studies, U.S. Department of Agriculture publications, and the SWC Appropriations Division. Aquifer boundaries are determined by SWC hydrologists and are being continually updated. The shallow aquifer dataset used in this study was retrieved on July 1, 2016 and does not reflect any changes made after that date.

There are three components to the monitoring score: Vulnerability, Sensitivity, and Risk. Each component is assigned a value, then combined to produce the final monitoring score. A total of 213 surficial aquifers were examined individually and assigned scores and ratings based on their individual component results. Each component had a range of results that yielded a Low, Moderate, or High rating, with a corresponding score of 1, 2, or 3. Rating thresholds were determined by creating three approximately equal-sized categories of 71 members. Vulnerability was the only component that had unevenly sized categories; the nature of the ratings allowed more than one aquifer to have identical results.

### ***Method Used to Determine Vulnerability Component***

The GTS uses the term “Vulnerability” to refer to the physical ease with which a contaminant can enter an aquifer (Pettyjohn et al., 1991). It was decided that the DRASTIC model, created by the U.S. Environmental Protection Agency (EPA) in 1985, would serve as the method of evaluating this component. DRASTIC is an acronym that stands for Depth to water, Recharge, Aquifer media, Soil media, Topography, Impact of the vadose zone, and hydraulic Conductivity (Aller et al., 1987). Based on correlations between DRASTIC scores and incidents of contamination in municipal wells, Kalinski et al. (1994) state that DRASTIC can be a valuable tool for identifying supplies that are vulnerable to contamination.

Each component of the DRASTIC model is assigned a numeric value, based upon a set of ranges and conditions. A summary of DRASTIC ranges and ratings organized by component can be found in Table 1 through Table 7.

## 2019 Geographic Targeting System

Table 1. Ranges and Ratings for Depth to Water

Depth to Water (Feet)	
Range	Rating
0 - 5	10
5 - 15	9
15 - 30	7
30 - 50	5
50 - 75	3
75 - 100	2
≥ 100	1

Table 2. Ranges and Ratings for Net Recharge

Net Recharge (Inches/Year)	
Range	Rating
0 - 2	1
2 - 4	3
4 - 7	6
7 - 10	8
≥ 10	9

Table 3. Ranges and Ratings for Aquifer Media

Aquifer Media	
Range	Rating
Massive Shale	2
Glacial Till	5
Bedded Sandstone and Shale Sequences	6
Massive Sandstone	6
Sand and Gravel	8

Table 4. Ranges and Ratings for Soil Media

Soil Media	
Range	Rating
Thin or Absent	10
Gravel	10
Sand	9
Peat	8
Shrinking and/or Aggregated Clay	7
Sandy Loam	6
Loam	5
Silty Loam	4
Clay Loam	3
Muck	2
Non-shrinking and Non-aggregated Clay	1

Table 5. Ranges and Ratings for Topography

Topography (Percent Slope)	
Range	Rating
0 - 2	10
2 - 6	9
6 - 12	5
12 - 18	3
≥ 18	1

Table 6. Ranges and Ratings for Impact of the Vadose Zone

Vadose Zone Media	
Range	Rating
Confining Layer	1
Silt/Clay	3
Shale	3
Bedded Sandstone and Shale	6
Sand and Gravel w/Significant Silt and Clay	6
Sand and Gravel	8

Table 7. Ranges and Ratings for Hydraulic Conductivity (Gallons Per Day)

<b>Hydraulic Conductivity (GPD/Ft<sup>2</sup>)</b>	
<b>Range</b>	<b>Rating</b>
1 - 100	1
100 - 300	2
300 - 700	4
700 - 1000	6
1000 - 2000	8
≥ 2000	10

Each of the assigned ratings is then multiplied by a weight constant (Formula 1). This produces a final numeric value that represents the aquifer's vulnerability to contamination; a higher number indicates more vulnerability, while a lower number represents less vulnerability.

*Formula 1: DRASTIC Formula*

$$DrDw + RrRw + ArAw + SrSw + TrTw + IrIw + CrCw = \text{DRASTIC Score (Unitless)}$$

(*r = rating, w = weight, D = Depth to water, R = Recharge, S = Sensitivity, T = Topography, I = Impact of vadose zone, C = hydraulic Conductivity*)

The GTS produces two DRASTIC scores for each aquifer — a Generic DRASTIC score and a Pesticide DRASTIC score. This is done by applying a different weight constant to each DRASTIC parameter (Table 8). A Generic DRASTIC score provides a general indication of aquifer vulnerability but may be less accurate for different contaminants. The Pesticide DRASTIC score has been adjusted to account for the chemical behavior of pesticides. For example, the weight value assigned to "Soil Media" in the generic DRASTIC model is 2, indicating a relatively low significance. However, in the Pesticide DRASTIC model, "Soil Media" is given a weight of 5, indicating a much higher significance. The Pesticide DRASTIC score was used as the Vulnerability component of the GTS.

Table 8. DRASTIC Parameter Weights for the "Generic" and "Pesticide" Iterations

<b>Parameter</b>	<b>Generic</b>	<b>Pesticide</b>
Depth to Water	5	5
Net Recharge	4	4
Aquifer Media	3	3
Soil Media	2	5
Topography	1	3
Impact of the Vadose Zone	5	4
Hydraulic Conductivity	3	2

The static nature of geologic characteristics permitted the reuse of certain 1997 GTS DRASTIC components. Some characteristics such as depth to water, soil media, and net recharge were reassessed to account for changes in precipitation patterns. This information was obtained from a variety of sources developed and maintained by the SWC. Once the data was located, it was entered in a spreadsheet that generated the final vulnerability scores using Formula 1. Once a Pesticide DRASTIC score had been calculated, a Vulnerability rating was assigned according to the ranges in Table 9.

Table 9. Vulnerability Rating for Pesticide DRASTIC Scores

DRASTIC Score Range	Rating
0-129	1 (Low)
130-159	2 (Moderate)
160+	3 (High)

#### ***Method Used to Determine Sensitivity Component***

In the context of the GTS, “Sensitivity” refers to the usage of agricultural chemicals (fertilizers, pesticides, herbicides, etc.). County data for the sale and use of agricultural chemicals was not available at the time of the 1997 GTS. Instead, a surrogate value of the sum of total market value of crop and livestock sales per acre was used, based on information summarized in the 1992 National Pesticides Survey Phase II Report (U.S. EPA, 1992). The agricultural surrogate was used again in 2019; however, there were changes to the methods of obtaining and transforming the data.

The United States Department of Agriculture (USDA) publishes county-level agricultural census data every five years (UDSA, 2014). The data used in the 2019 GTS was taken from the 2012 Agricultural Census. A total agricultural production value was calculated by summing crop and livestock sales for all counties. Production was then divided by the number of farmed acres within a county to produce a production-per-farmed-acre (production/acre) value. This was a slight change from the 1997 GTS, which used total county acres. The change was made to better account for intensity and density of agricultural practices within a county.

Once a value had been generated for each county, the data was transformed to the aquifer scale. In cases where an aquifer lay entirely within county boundaries, the production/acre value was assigned to the aquifer. However, many aquifers cross county boundaries, requiring new production/acre values to be calculated. In these instances, a partial production value was assigned to each portion of the aquifer present in a different county, and the partial production values were then summed to obtain a single production/acre value (Formula 2).

***Formula 2: Aquifer Production Value Calculation***

$$AQ_{PAR} = CO_{PROD} * AQ_P \quad - \cdot \cdot \cdot \rightarrow \quad AQ_{PROD} = \sum AQ_{PAR}$$

(AQ = Aquifer, AQ<sub>PAR</sub> = Partial production/acre value, AQ<sub>PROD</sub> = Aquifer production/acre value,

CO<sub>PROD</sub> = County production/acre value, AQ<sub>P</sub> = Proportion of aquifer in county)

The large number of aquifers being analyzed would have made this an impractical task to complete by hand. Instead, a model was developed using ArcGIS 10.3 that automatically assigned production/acre values based on these methods. This model generated a data table that could be uploaded into Excel 2007 for use in calculating the final monitoring score. The range thresholds were determined by creating three approximately equal-sized categories of the aquifers based on their respective sensitivity surrogate values in dollars/farmed acre (Table 10).

Table 10. Sensitivity Rating for the Market Value of Production Per Farmed Acre

Range (dollar/farmed acre)	Rating
0-202.14	1 (Low)
202.15-356.91	2 (Moderate)
356.92+	3 (High)

***Method Used to Determine Risk Component***

“Risk” is defined as the economic value of the loss of the groundwater resource should contamination occur. The 1997 GTS used the total amount of water appropriated from an aquifer in acre-feet, but this was changed in the 2019 GTS. Contamination of a groundwater resource is not likely to occur evenly throughout an aquifer, especially those with large surface areas. To account for this, the Risk component was redefined as the amount of water appropriated per square mile (acre-feet/mi<sup>2</sup>) (Table 11).

Table 11. Risk Rating for Appropriated Water Per Square Mile

Range (acre-feet/mi <sup>2</sup> )	Rating
0-1.24	1 (Low)
1.244-33.51	2 (Moderate)
33.52+	3 (High)

For example, the Central Dakota aquifer has a total surface area of approximately 683 mi<sup>2</sup>, with a total permitted water volume of 77,015 acre-feet. The Central Dakota aquifer is the single largest aquifer analyzed and has the greatest appropriated water volume. When the permitted water

volume is examined on a square-mile basis, it has a value of approximately 112.81 acre-feet/mi<sup>2</sup>, ranking 37<sup>th</sup>.

Compare this to the Jamestown aquifer, which has a surface area of 10.45 mi<sup>2</sup>, 17,993 permitted acre-feet, and a value of 1,715 acre-feet/mi<sup>2</sup>. The Central Dakota aquifer is six times the surface area of the Jamestown aquifer, but the Jamestown aquifer permits 15 times more water use per square mile. By this reasoning, contamination would impact water use in the Jamestown aquifer more than in the Central Dakota aquifer.

#### ***Method Used to Calculate Total Monitoring Score***

Each monitoring score component was divided into three equally sized categories with a corresponding numeric value: Low (1), Moderate (2), and High (3). The three numeric values were added together, resulting in a total monitoring score (Table 12).

Table 12. Total Monitoring Score and Priority

Score	Priority
3-4	Low
5-7	Moderate
8-9	High

Using the Inkster aquifer as an example, the determinations of the pesticide DRASTIC score and total GTS monitoring score are shown in Table 13.

Table 13. Example of Geographic Targeting System Scoring for the Inkster Aquifer, North Dakota

<b>SETTING: Inkster Aquifer, Grand Forks County</b>				
FACTOR	VALUE	RATING	WEIGHT	SCORE
Depth to Water	28'	7	5	35
Net Recharge	5.604"	6	4	24
Aquifer Media	sand and gravel	8	3	24
Soil Media	sandy loam	6	5	30
Topography	1%	10	3	30
Impact of Vadose Zone	sand & gravel	8	4	32
Conductivity	1,500 gpd/ft <sup>2</sup>	8	2	16
Pesticide DRASTIC score		HIGH		191
Chemical Use Surrogate	\$525.20/acre	HIGH		3
Permitted Water Use	28.27 ac. ft.	HIGH		3
<b>Total GTS Monitoring Score</b>	<b>9</b>	<b>HIGH</b>		<b>9</b>

### ***Comparison to 1997 Results***

GTS monitoring scores are not directly comparable to other iterations. However, it is valuable to understand how an aquifer may have changed in overall monitoring priority. A total of 180 aquifers were assessed in both the 1997 and 2019 GTS. Many of these aquifers experienced changes to boundaries, appropriations, and land use. In cases where multiple aquifers were merged into one (e.g., the Central Dakota aquifer being created from the Marstonmoor Plain and Tappen aquifers), the highest monitoring priority value was used. In the Central Dakota aquifer example, the Marstonmoor Plain aquifer had a total monitoring score of 8, while the Tappen aquifer had a score of 5. When comparing the Central Dakota aquifer 2019 monitoring score to the 1997 score, the Marstonmoor Plain score of 8 was compared to the 2019 Central Dakota score of 8, showing that the aquifer had not changed in priority.

### ***Changes in Methodology from the 1997 GTS Study***

The slight changes in methodology for the Sensitivity and Risk components were made to improve the effectiveness of the total monitoring score. Once the changes were implemented, and the component and final monitoring scores had been calculated, the scores were evaluated using Spearman's correlation. This non-parametric correlation statistic supported the changes made to the methods by showing an increase in correlation to historic pesticide detections, in comparison to the original 1997 methods.

## **RESULTS**

A total of 213 aquifers or aquifer sections were assessed in the 2019 GTS. DRASTIC inputs and results can be found in Attachment 1. The GTS inputs and results can be found in Attachment 2. Of the 213 aquifers, 139 were designated as Moderate Priority, 40 Low Priority, and 34 High Priority. A total of 115 aquifers evaluated in both the 1997 and 2019 GTS studies had differing monitoring scores. Seventy-eight aquifers increased in overall monitoring score, and 37 decreased. Of the 115 aquifers that changed monitoring scores, 50 changed monitoring priorities, 25 increased in monitoring priority, and 25 decreased in monitoring priority.

## **DISCUSSION**

The GTS is a relative, ordinal classification system used as an administrative tool for directing sampling activities of the AAMP. While components of the GTS are used for regulatory purposes by other programs, such as the North Dakota Underground Injection Control Program, the total monitoring score of the GTS has no regulatory implications. Instead, it is a summary of surficial groundwater resources across the state at the time of completion. A Low monitoring priority in the 1997 GTS is not directly comparable to a Low monitoring priority in the 2019 GTS. However, it is useful for assessing how monitoring importance has changed over time and to ensure that state resources are utilized effectively.

A High monitoring priority does not necessarily indicate that an aquifer is more likely to be contaminated. Of the three components of the GTS, only Vulnerability and Sensitivity directly address the contamination of an aquifer. Risk is purely an economic factor, but it remains an important consideration. Aquifers are utilized for many purposes in North Dakota including municipal water and irrigation, and it is important to consider these uses when selecting monitoring sites.

As an administrative tool, there are scientific limitations to the GTS. The large-scale nature of the project did not allow for an in-depth examination of all data collected. The geologic properties studied as part of the DRASTIC are primarily available only when detailed subsurface examinations are made. This study used existing data from the SWC; additional geologic investigations were not conducted for this study. In some instances, the methods used for data collection and analysis may be misleading. For example, depth to water can be downloaded from thousands of SWC monitoring sites, but this information may not be indicative of the actual depth to water-bearing material in confined or semi-confined aquifers. Therefore, a review of drilling logs associated with confined aquifers was conducted to determine the average depth to water-bearing material.

Sensitivity in the GTS is not a direct measurement of chemical applications but is instead a surrogate value. While this surrogate value is supported in research, a direct measurement of chemical application would be more appropriate but is unfortunately unavailable. In addition to chemical applications, the GTS does not take into consideration the fate of contaminants within an aquifer. Geochemical characteristics of the aquifers, which were not examined during the GTS, may have effects on the fate of contaminants within an aquifer.

Despite the limitations, the GTS is an excellent tool for assessing areas of high monitoring importance. The abundance and nature of the groundwater resources in North Dakota make monitoring of groundwater quality a necessity to protect human and environmental health. Using the GTS as a guide, the AAMP will be able to direct monitoring efforts where they will be most beneficial to the people of North Dakota.
