### MICROBIOME MANAGEMENT FOR IMPROVED NUTRIENT-USE EFFICIENCY AND WATER QUALITY Project Implementation Plan Summary

PI: Samiran Banerjee Co-PIs: Aaron Daigh, Blaine Schatz

#### Summary

The conventional agricultural system in North Dakota (ND) is a success story in many ways, with ND leading the nation in yields of spring wheat, beans, canola as well as many other agricultural and livestock products. While a steadily increasing production capacity is well-supported by a dynamic agriculture sector, poor nutrient-use-efficiency (NUE) remains a major challenge. In particular, nutrient losses via leaching of water (i.e., nitrogen and phosphorus) from agroecosystems caused by low NUE has resulted in undesirable effects on the environment. As much as 57% and 69% of the ND rivers and streams were found in 'poor' conditions due to excess nitrogen and phosphorus, respectively. Runoff, drainage and leachate from croplands and animal feeding operations were identified as major contributors to the excess nutrients, highlighting the lack of effective nutrient management strategies and an urgent need for sustainable practices in ND agricultural systems. In addition to hydrological and soil chemical factors, nutrient losses can also be determined by nutrient-use efficiency and soil biological parameters. However, the importance of soil biological activities for managing intensive agricultural systems has received little recognition until now. Sustainable intensification of agroecosystems aims to alleviate environmental footprints through targeted utilization of soil biological traits. Microbiomes are an indispensable component of agroecosystem functioning and thus can be an important tool to achieve agricultural sustainability. The proposed study aims to use a long-term field trial at the Carrington Research and Extension Center and strategic sampling of several farmlands in the region to understand how the timing and rates of nutrient applications can influence plant- and soil microbiomes and vice versa. Our study aims to reveal how key microbial players can be manipulated to enhance nitrogen- and phosphorus-use-efficiency, decrease their losses to water bodies, and improve the water quality in ND. The overall goal of this project is to enhance water quality by optimizing microbial contributions and alleviating nutrient losses from ND agroecosystems. The project will monitor changes in water quality in response to various timing and rates of fertilizer applications across cropping systems. It will identify the cropping practices that are optimal in enhancing soil biological contributions for efficient nutrient uptake in various soil conditions. Specifically, we will be addressing the following objectives: a) exploring the relationships among microbial communities, nutrient-use efficiency and water quality under various agricultural management practices, hydrological and soil conditions; and b) disseminating results and findings to producers and landowners in ND, and to promote awareness about the importance of microbiomes for nutrient-use efficiency and water quality. Knowledge generated will be disseminated to ND farmers and stakeholders using existing outlets and networks at NDSU to enhance awareness regarding the microbial roles in reducing nutrient losses from agricultural systems. We will also formulate recommendations for various soil types and agronomic practices.

## **3.0 PROJECT DESCRIPTION**

## 3.1 Project Goals

The overall goal of this project is to enhance water quality by optimizing microbial contributions and alleviating nutrient losses from ND agroecosystems. The project will monitor changes in water quality in response to various timing and rates of fertilizer applications across cropping systems. It will identify the cropping practices that are optimal in enhancing soil biological contributions for efficient nutrient uptake in various soil conditions. It aims to harness key players in the plant and soil microbiomes through management practices to mitigate future water quality impairment in ND. By incorporating seasonal patterns, the project aims to develop models linking pedological and agronomical data to microbial characteristics. Knowledge generated will be disseminated to ND farmers and stakeholders using existing outlets and networks at NDSU to enhance awareness regarding the microbial roles in reducing nutrient losses from agricultural systems. We will formulate recommendations for various soil types and agronomic practices. Such tailored recommendations will facilitate producers to understand nutrient loss patterns in their farmlands and make informed decisions. This will potentially enable them to readjust fertilizer inputs, reduce the cost of related agricultural practices, and reduce externalities that have consequences to water resources. Furthermore, the linkage between agricultural microbiomes and water quality is a key watershed management priority and yet an underexplored area. The project aims to fill this informational void. In particular, it will create opportunities to disseminate outcomes at regional and national meetings on watershed and natural resource management.

### 3.2 Objectives

The project will use a combination of exploratory field surveys and experimental manipulations at farmlands and a long-term field trial, respectively, to achieve the integrated objectives outlined below. Note that these objectives are integral to the project goal and are not intended to be interpreted as independent components. A long-term agricultural field trial at the Carrington Research Extension Center (CREC) of NDSU will be the primary site. Additionally, several farmlands will be selected across soil types and management practices for monitoring the linkage observed at the long-term experimental site. The synergistic use of these sites under different soil types and weather conditions will be a unique strength of this study. Furthermore, a range of physical, chemical and molecular techniques will be used to assess hydrological, edaphic, agronomic, and biological properties. Such comprehensive measurement will also be a strength of this project. All information and data will be summarized and disseminated to landowners, agricultural producers, state and county extension agents, and the ND Department of Environmental Quality personnel for educational events to the general public and stakeholders.

**Objective 1:** To explore the relationships among microbial communities, nutrient-use efficiency and water quality under various agricultural management practices, hydrological and soil conditions.

**Task 1:** This task will explore the link between microbial communities and hydrological properties across several farms and in a long-term soil management and crop rotation field trial at the Carrington Research Extension Center (CREC) of NDSU.

**Task 2:** This task will monitor the seasonal patterns of hydrological and edaphic properties across a management intensity gradient.

# **Objective 2:**

To disseminate results and findings to producers and landowners in ND, and to promote awareness about the importance of microbiomes for nutrient-use efficiency and water quality. **Task 3:** As part of this task, we will make educational materials on the overall importance of agricultural microbiomes for soil nutrient cycling processes with subsequent implications for water quality.
